DIABETES UK
KNOW DIABETES. FIGHT DIABETES.

DIABETES REMISSION

American Diabetes Association®
Connected for Life

Diabetes remission in people with type 2 diabetes means that your blood sugar levels are healthy without needing to take any diabetes medication.

People with type 2 diabetes should be considered in remission after sustaining normal blood glucose (sugar) levels for three months or more, according to a new consensus statement from the American Diabetes Association® (ADA), the Endocrine Society, the European Association for the Study of Diabetes and Diabetes UK jointly published in *Diabetes Care*, the *Journal of Clinical Endocrinology & Metabolism*, *Diabetologia*, and *Diabetic Medicine*, respectively.

กรมควบคุมโรค
Department of Disease Control

สำนักงานป้องกันควบคุมโรคที่ 9 จังหวัดนครราชสีมา

ประชุมเชิงปฏิบัติการพัฒนาศักยภาพบุคลากรทางการแพทย์ และการสาธารณสุข ในการเข้าถึง ป้องกัน ควบคุมโรคเบาหวานชนิดที่ 2 ให้เข้าสู่โรคเบาหวานระยะสงบ ด้วยการปรับเปลี่ยนพฤติกรรมอย่างเข้มงวด (DM Remission)

ระหว่างวันที่ 13 – 14 กุมภาพันธ์ 2567 เวลา 08.00 - 20.00 น.

กลุ่มเป้าหมาย

ทีมสหวิชาชีพ : แพทย์ทั่วไปหรือหมอครอบครัว,หัวหน้ากลุ่มภารพยาบาล, หัวหน้าคลินิก NCDs, เภสัชกร, พยาบาลประจำคลินิก NCDs, พยาบาลรับผิดชอบงาน NCDs สสอ./รพสต. และ นักโภชนาการ/นักโภชนากร รวม 7 ท่าน/ทีม

รุ่นที่ 1 ทีมสหวิชาชีพจังหวัดนครราชสีมาและจังหวัดชัยภูมิ
สถานที่ : ณ ห้องประชุมโรงแรมสีมาธานี อำเภอเมืองนครราชสีมา จังหวัดนครราชสีมา

รุ่นที่ 2 ทีมสหวิชาชีพจังหวัดบุรีรัมย์และจังหวัดสุรินทร์
สถานที่ : ณ ห้องประชุมโรงแรมเซ็นทารา โคราช อำเภอเมืองนครราชสีมา จังหวัดนครราชสีมา

ประธานเปิดโครงการประชุม

นายแพทย์ภูวเดช สุระโคตร
ผู้ตรวจราชการกระทรวงสาธารณสุข เขตสุขภาพที่ 9

กล่าวรายงานและวัตถุประสงค์ของโครงการฯ

นายแพทย์ทวีชัย วิษณุโยธิน
ผู้อำนวยการ
สำนักงานป้องกันควบคุมโรคที่ 9 จังหวัดนครราชสีมา

วิทยากร

นายแพทย์ธนศักดิ์ ยิ้มเกิด
ที่ปรึกษาโครงการรักษาเบาหวานเข้าสู่ภาวะสงบของ สปสช. / DietDoctor Thailand

นายแพทย์ภูวดล พลพวก
รองนายแพทย์สสจ.พิษณุโลก
ด้านเวชกรรมป้องกัน
และผู้อำนวยการโรงพยาบาลบางระกำ

นายแพทย์ชัชวาล ลีลาเจริญพร
ข้าราชการบำนาญ

ทีมวิทยากร โรงเรียนเบาหวานภูวดลโมเดล

ทีมวิทยากร โรงเรียนเบาหวานวิทยา อำเภอพิมาย

ประโยชน์ที่จะได้รับ :
บุคลากรทางการแพทย์ การสาธารณสุข มีความรู้เรื่องการเฝ้าระวัง ป้องกันควบคุมโรคเบาหวานชนิดที่ 2 ให้เข้าสู่โรคเบาหวานระยะสงบ ด้วยการปรับเปลี่ยนพฤติกรรมอย่างเข้มงวด (DM Remission) สามารถนำไปใช้ในการรักษาผู้ป่วยโรคเบาหวานในคลินิกได้

เนื้อหา :
รูปแบบการอบรมมีทั้งภาคทฤษฎีและภาคปฏิบัติ โดยวิทยากรที่มีความรู้ความเชี่ยวชาญและประสบการณ์ที่เกี่ยวข้องกับการดูแลรักษาผู้ป่วยเบาหวานชนิดที่ 2 ให้เข้าสู่โรคเบาหวานระยะสงบ

ประกาศนียบัตร :
ผู้ผ่านการอบรมได้รับประกาศนียบัตร (ในรูปแบบไฟล์)

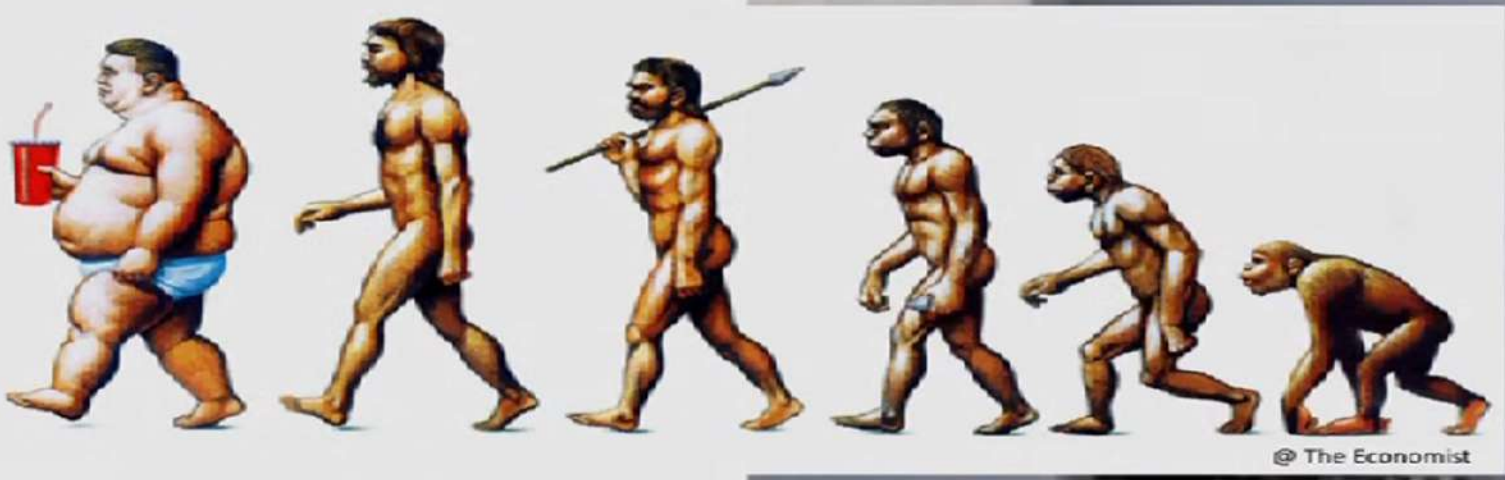
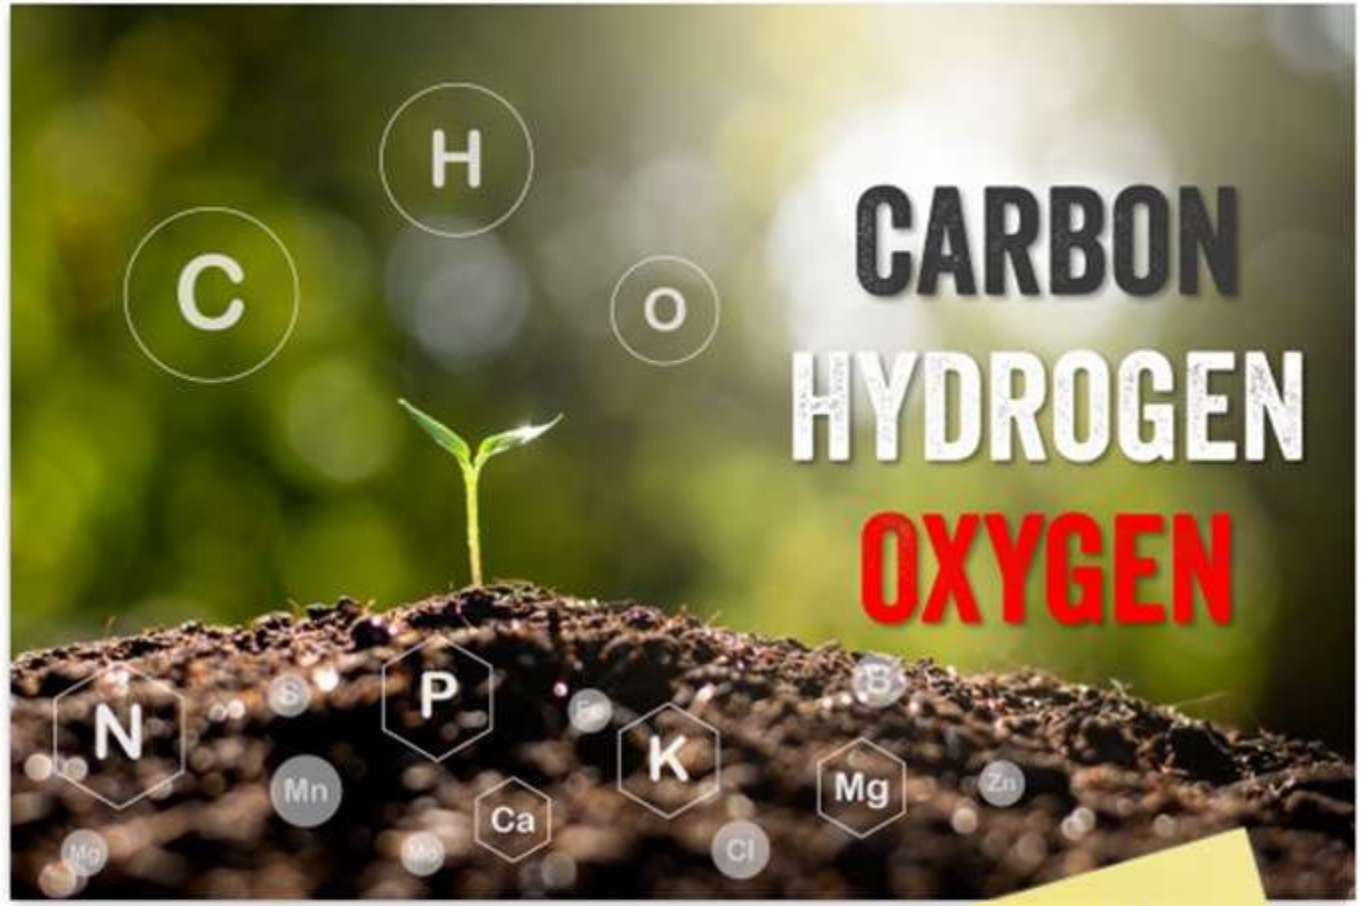
Human Diet
And
Why we get sick?

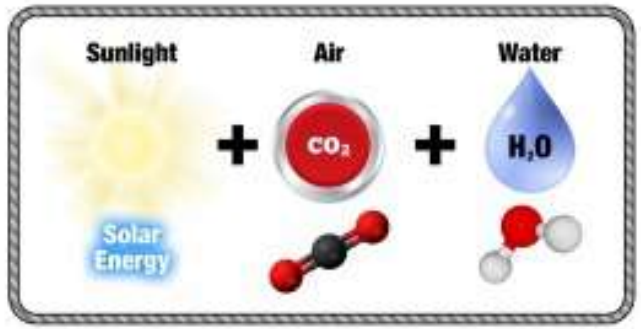


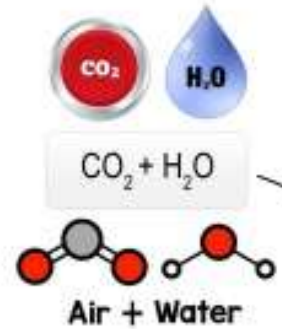


CARBON, HYDROGEN, AND OXYGEN ARE THE THREE MAIN ELEMENTS OF LIFE.

PLANTS GET THESE FROM AIR AND WATER.

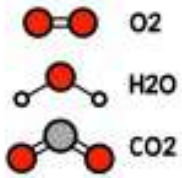
All dietary energy is solar energy, captured by plants, as the high-energy carbon-carbon and carbon-hydrogen bonds in carbohydrates and hydrocarbons (carbohydrates and fats).





Plants store solar energy using the three main elements of life: carbon, hydrogen, and oxygen.

- Carbon
- Hydrogen
- Oxygen



Energy-containing carbon-carbon and carbon-hydrogen bonds

Solar Energy stored as high-energy bonds

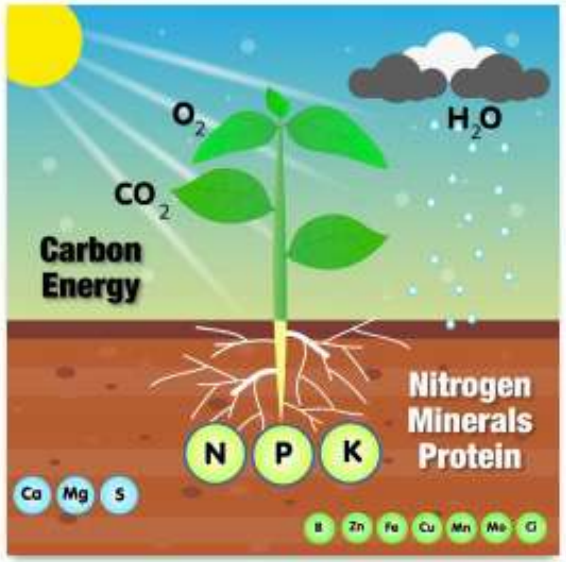
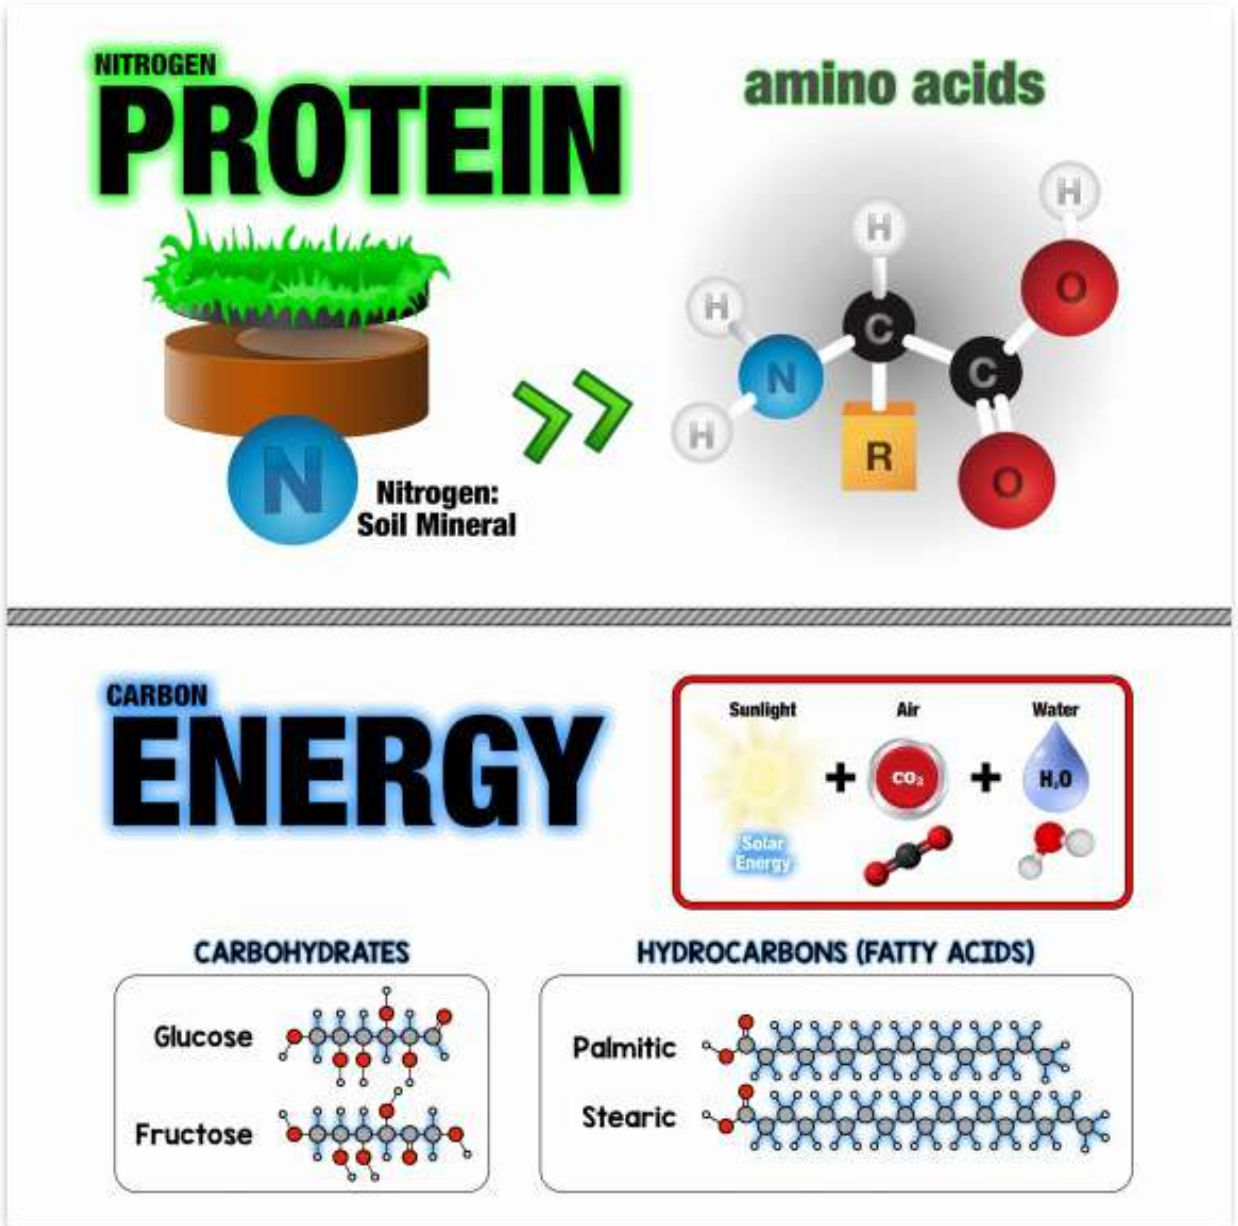
Solar Energy
Carbon for ENERGY
stored as carbon bonds in carbohydrates and fats
Nitrogen for PROTEIN
+ other minerals necessary for life
PROTEIN



Your body, as well, has a protein quantity and an energy quantity. Your basic body composition goal should be to achieve the HIGHEST lean mass at the LOWEST fat mass, so the protein to energy ratio of your body is going to be an important concept going forward.



All life on earth depends on nitrogen and minerals from the nutrient pool (soil etc).

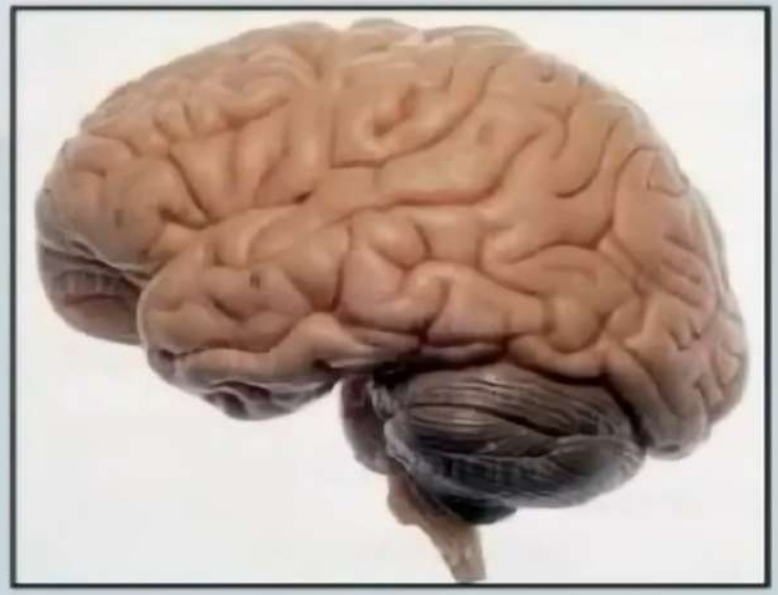
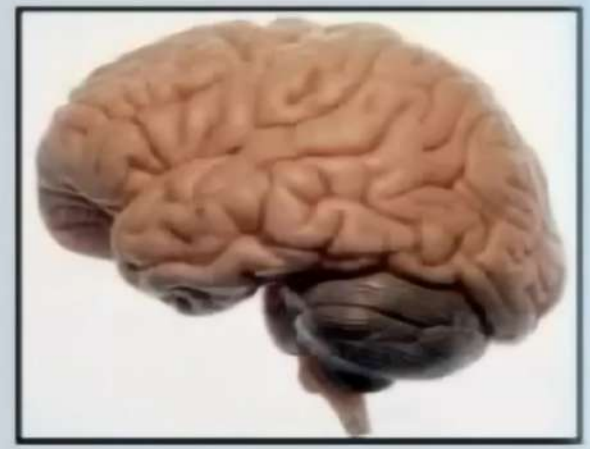
Nitrogen and Mineral Nutrient Pool



Why Did It Happen?

Where Does Energy For Brain Come From?

- **Our total energy intake is in accordance with Kleiber's Law**
- Brain is ~2% of total body weight
- Brain uses ~20-25% of total resting energy
- Small gut to compensate



- Very nutrient and energy dense diet needed
- Fat is the only macronutrient
- Animals the only practical source

Vegetable Fats Are Not Suitable

- **20** and **22** carbon fatty acids (AA, DTA, EPA, DHA) are essential for brain development – found only in animal foods
- Longest chain in vegetable oils – linoleic acid (n-6) and alpha-linolenic acid (n-3) are **18** carbon fatty acids
- **Obligate carnivores and humans "maintain an inefficient ability to chain elongate and desaturate 18 carbon fatty acids to their product 20 and 22 carbon fatty acids . . ."**
- **". . . preformed dietary 20 and 22 carbon fatty acids (found only in animal foods) were increasingly incorporated in lieu of endogenously synthesized fats derived from 18 carbon plant fatty acids."**
- **Our brain growth could never have happened without these fats**

Emken, R.A., Adlof, R.O., Rohwedder, W.K., and Gulley, R.M., Comparison of linolenic and linoleic acid metabolism in man: Influence of dietary linoleic acid. In: Sinclair, A., and Gibson, R. (Eds.), *Essential Fatty Acids and Eicosanoids*. Invited Papers from the Third International Conference. AOCS Press, Champaign IL: 1992, pp. 23–25.

ABSTRACT

Objectives: National dietary guidelines were introduced in 1977 and 1983, by the US and UK governments, respectively, with the ambition of reducing coronary heart disease (CHD) by reducing fat intake. To date, no analysis of the evidence base for these recommendations has been undertaken. The present study examines the evidence from randomised controlled trials (RCTs) available to the US and UK regulatory committees at their respective points of implementation.

KEY MESSAGES

What is already known about this subject?

- Dietary recommendations were introduced in the US (1977) and in the UK (1983) to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

What does this study add?

- No randomised controlled trial (RCT) had tested

ABSTRACT

Objectives: National dietary guidelines were introduced in 1977 and 1983, by the US and UK governments, respectively, with the ambition of reducing coronary heart disease (CHD) by reducing fat intake. To date, no analysis of the evidence base for these recommendations has been undertaken. The present study examines the evidence from randomised controlled trials (RCTs) available to the US and UK regulatory committees at their respective points of implementation.

Methods: A systematic review and meta-analysis were undertaken of RCTs, published prior to 1983, which examined the relationship between dietary fat, serum cholesterol and the development of CHD.

Results: 2467 males participated in six dietary trials: five secondary prevention studies and one including healthy participants. There were 370 deaths from all-cause mortality in the intervention and control groups. The risk ratio (RR) from meta-analysis was 0.996 (95% CI 0.865 to 1.147). There were 207 and 216 deaths from CHD in the intervention and control groups, respectively. The RR was 0.989 (95% CI 0.784 to 1.247). There were no differences in all-cause mortality and non-significant differences in CHD mortality, resulting from the dietary interventions. The reductions in mean serum cholesterol levels were significantly higher in the intervention groups; this did not result in significant differences in CHD or all-cause mortality. Government dietary fat recommendations were untested in any trial prior to being introduced.

Conclusions: Dietary recommendations were introduced for 220 million US and 56 million UK citizens by 1983, in the absence of supporting evidence from RCTs.

KEY MESSAGES

What is already known about this subject?

- Dietary recommendations were introduced in the US (1977) and in the UK (1983) to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

What does this study add?

- No randomised controlled trial (RCT) had tested government dietary fat recommendations before their introduction. Recommendations were made for 276 million people following secondary studies of 2467 males, which reported identical all-cause mortality. RCT evidence did not support the introduction of dietary fat guidelines.

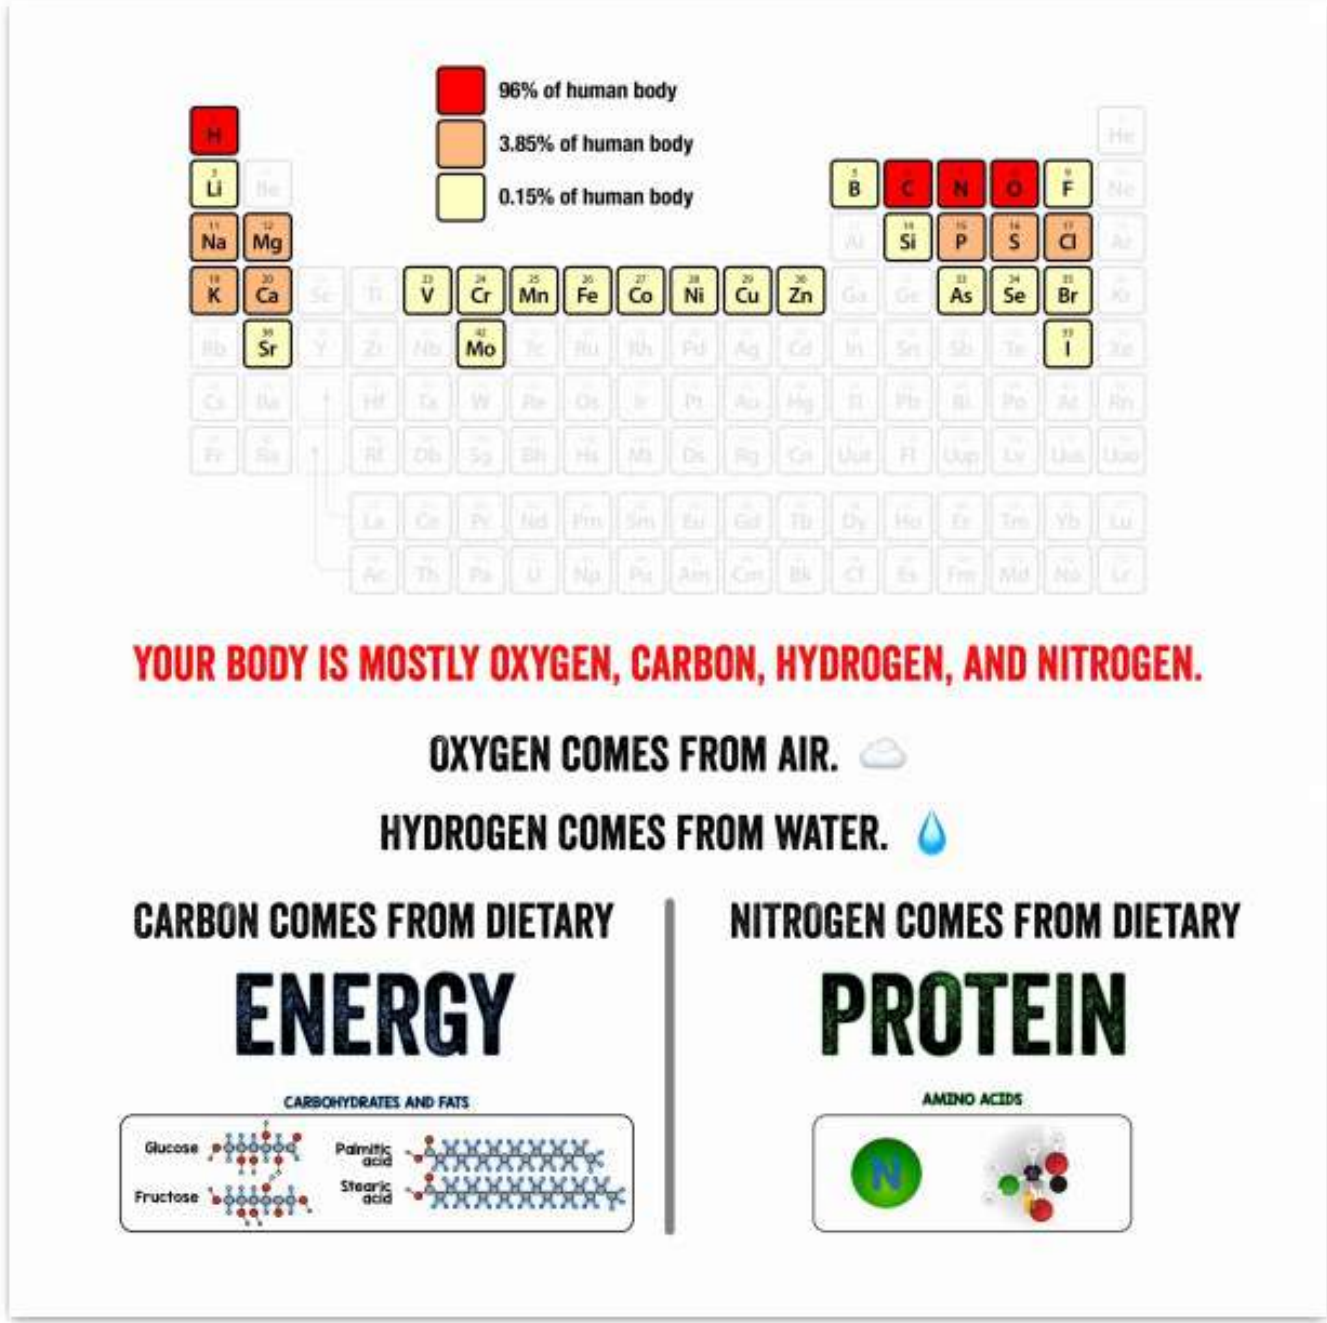
How might this impact on clinical practice?

- Clinicians may be more questioning of dietary guidelines, less accepting of low-fat advice (concomitantly high carbohydrate) and more engaged in nutritional discussions about the role of food in health.

INTRODUCTION

US public health dietary advice was advice issued by the National Advisory Committee on Nutritional Education in 1983.[2] The dietary recommendations in both cases focused on reducing dietary fat intake; specifically to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

The recommendations were an attempt to address the incidence of coronary heart disease (CHD). Both documents acknowledged that the evidence was not conclusive. Hegsted's introduction to the Dietary Goals for the US noted "there will undoubtedly be



Carbon, hydrogen, oxygen, and all of the ENERGY they contain comes from AIR, WATER, and SUNLIGHT. All of your nitrogen and other elements, necessary for PROTEIN, come from soil and the EARTH.

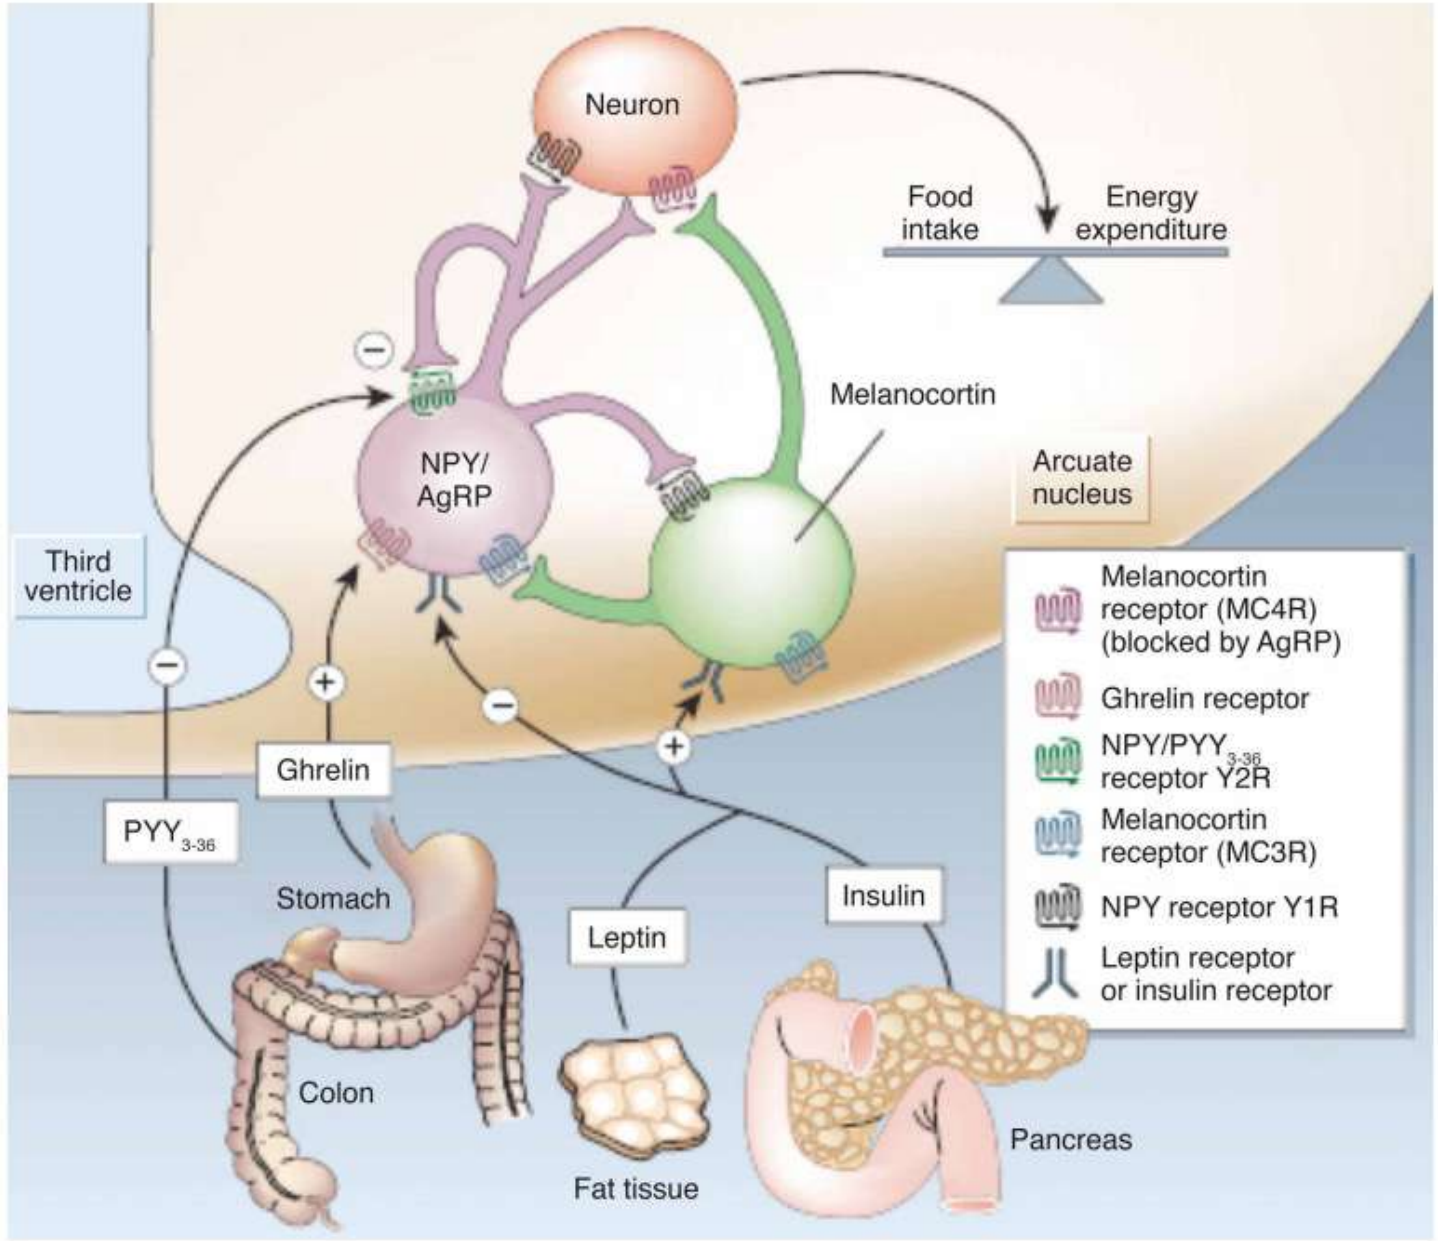

FIGURE 2 | Hypothalamic control of global energy balance. Appetite is regulated by a complex feed-back loop involving endocrine signals originated in peripheral tissues and intrahypothalamic peptides. Leptin and insulin inhibit the orexigenic NPY/AgRP neurons (purple) and stimulate the anorexigenic melanocortin neurons (green), resulting in a reduction of food intake. Ghrelin or $PYY_{3–36}$ activate or inhibit the NPY/AgRP neurons resulting in orexigenic or anorexigenic responses, respectively. Taken from Schwartz and Morton (2002). Reproduced with permission of the publisher.

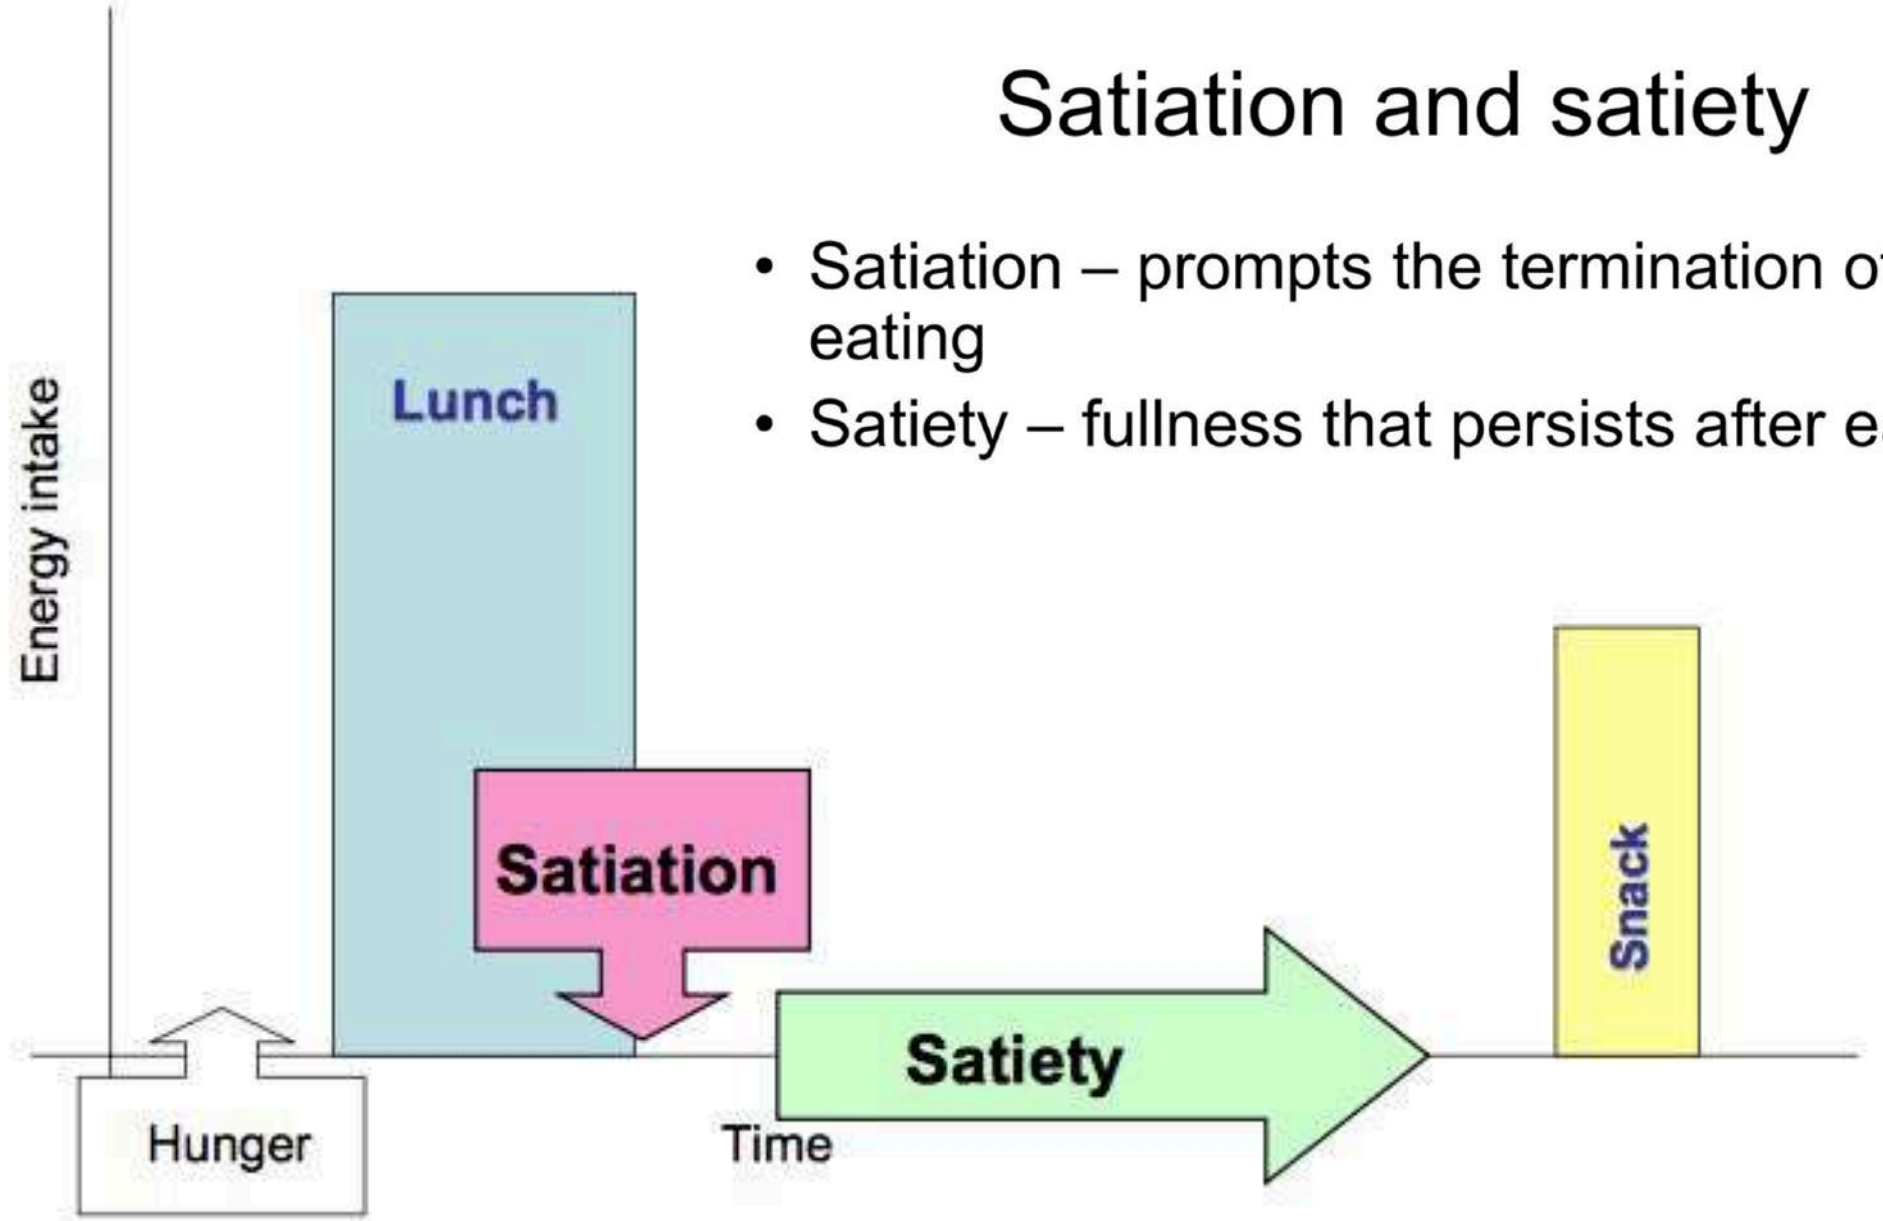
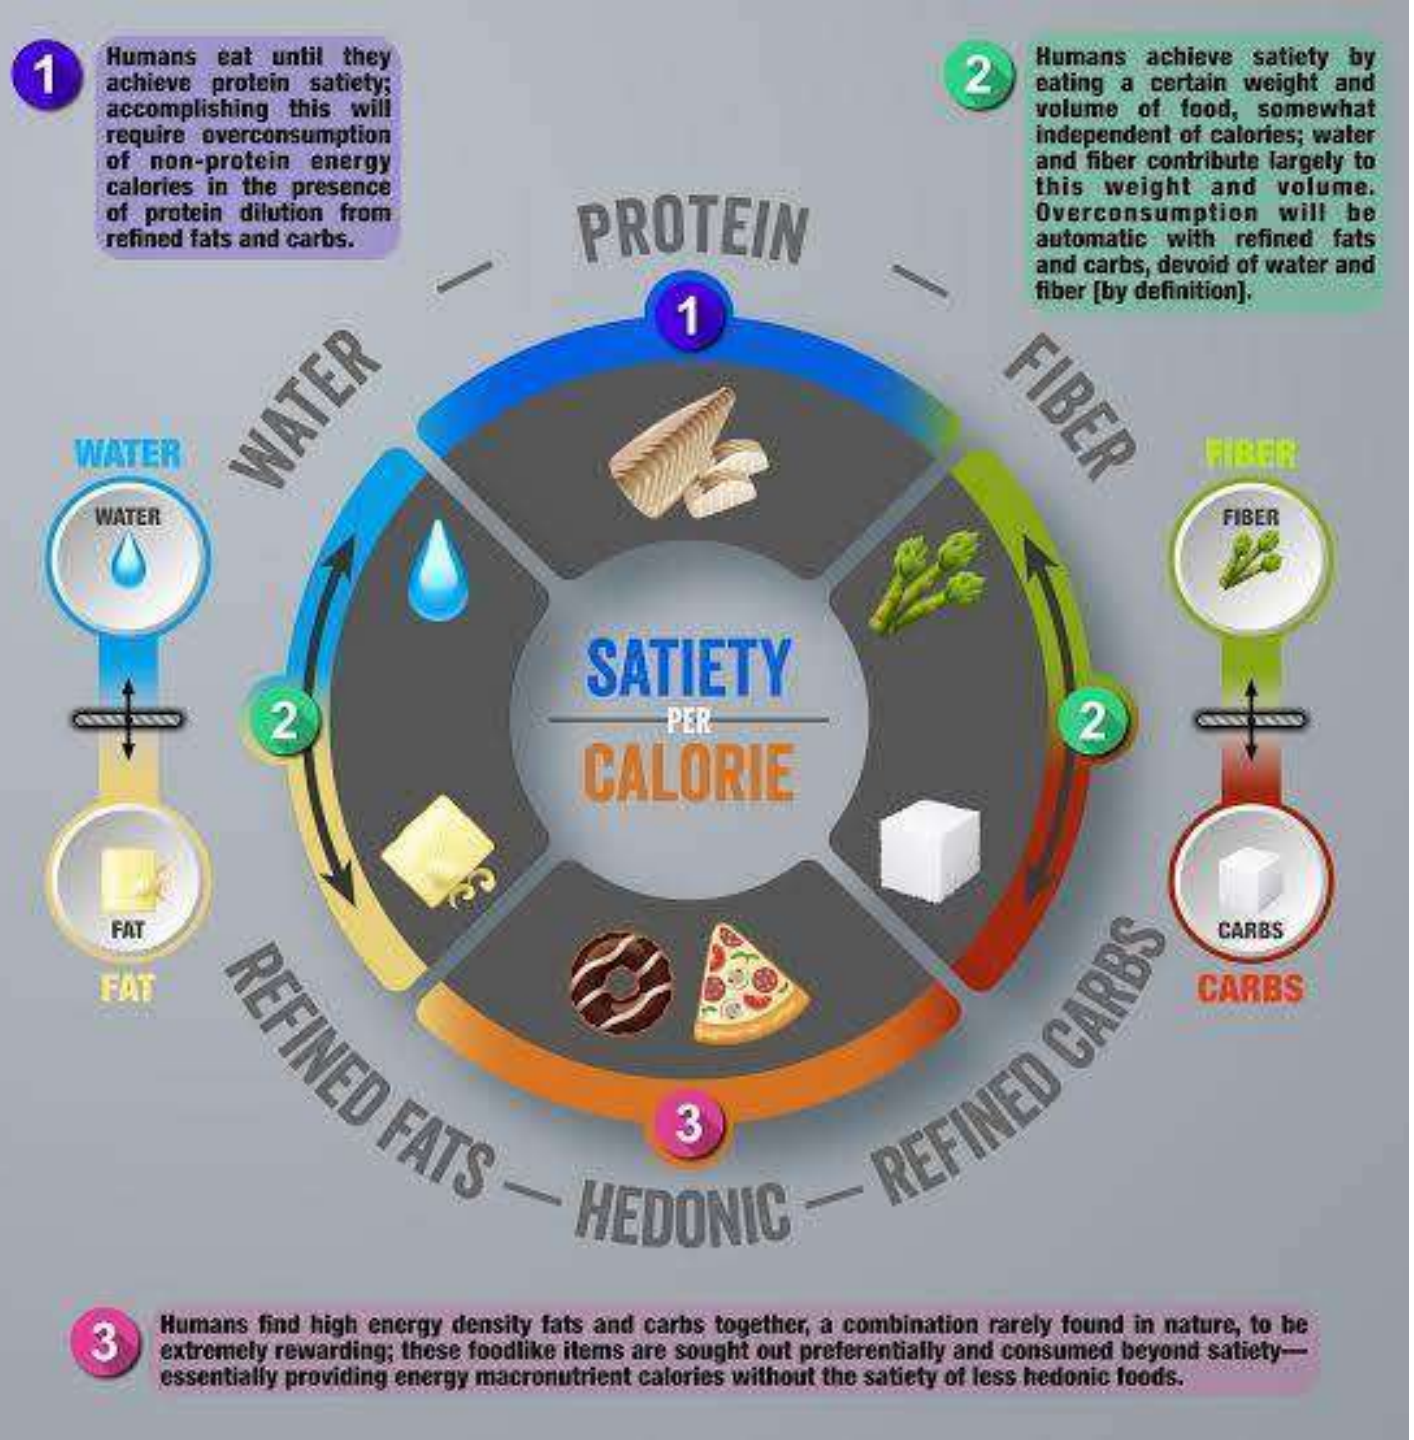
What are satiation and satiety?



Satiation and satiety

- Satiation – prompts the termination of eating
- Satiety – fullness that persists after eating



1
Humans eat until they achieve protein satiety; accomplishing this will require overconsumption of non-protein energy calories in the presence of protein dilution from refined fats and carbs.
2
Humans achieve satiety by eating a certain weight and volume of food, somewhat independent of calories; water and fiber contribute largely to this weight and volume. Overconsumption will be automatic with refined fats and carbs, devoid of water and fiber [by definition].

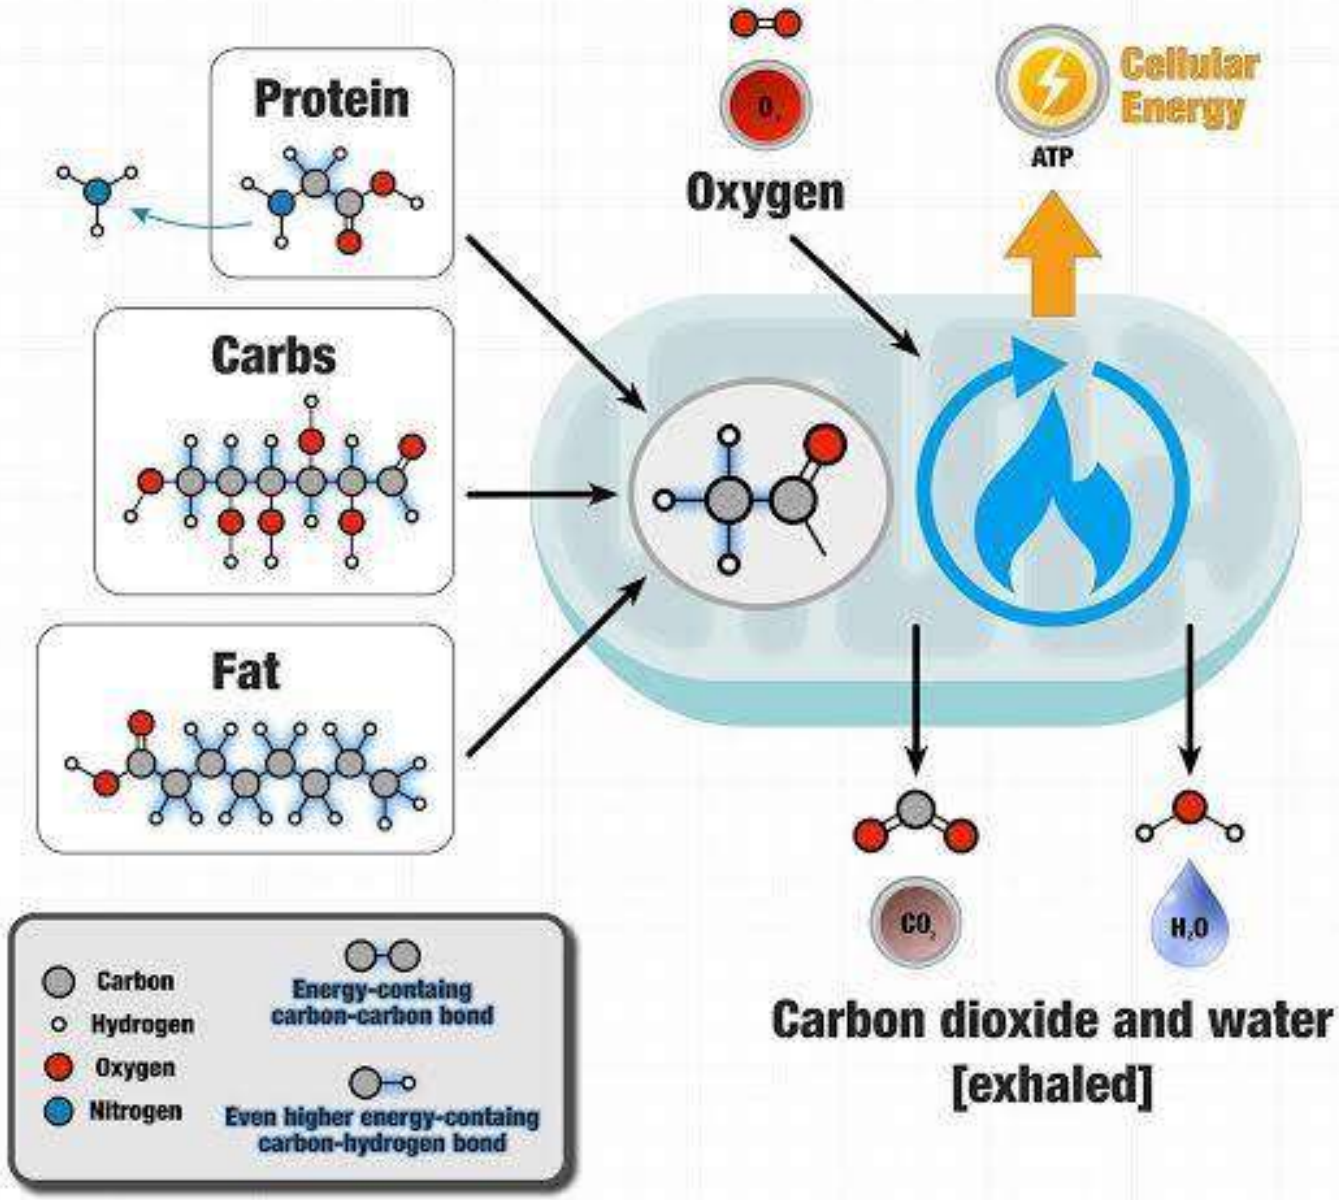
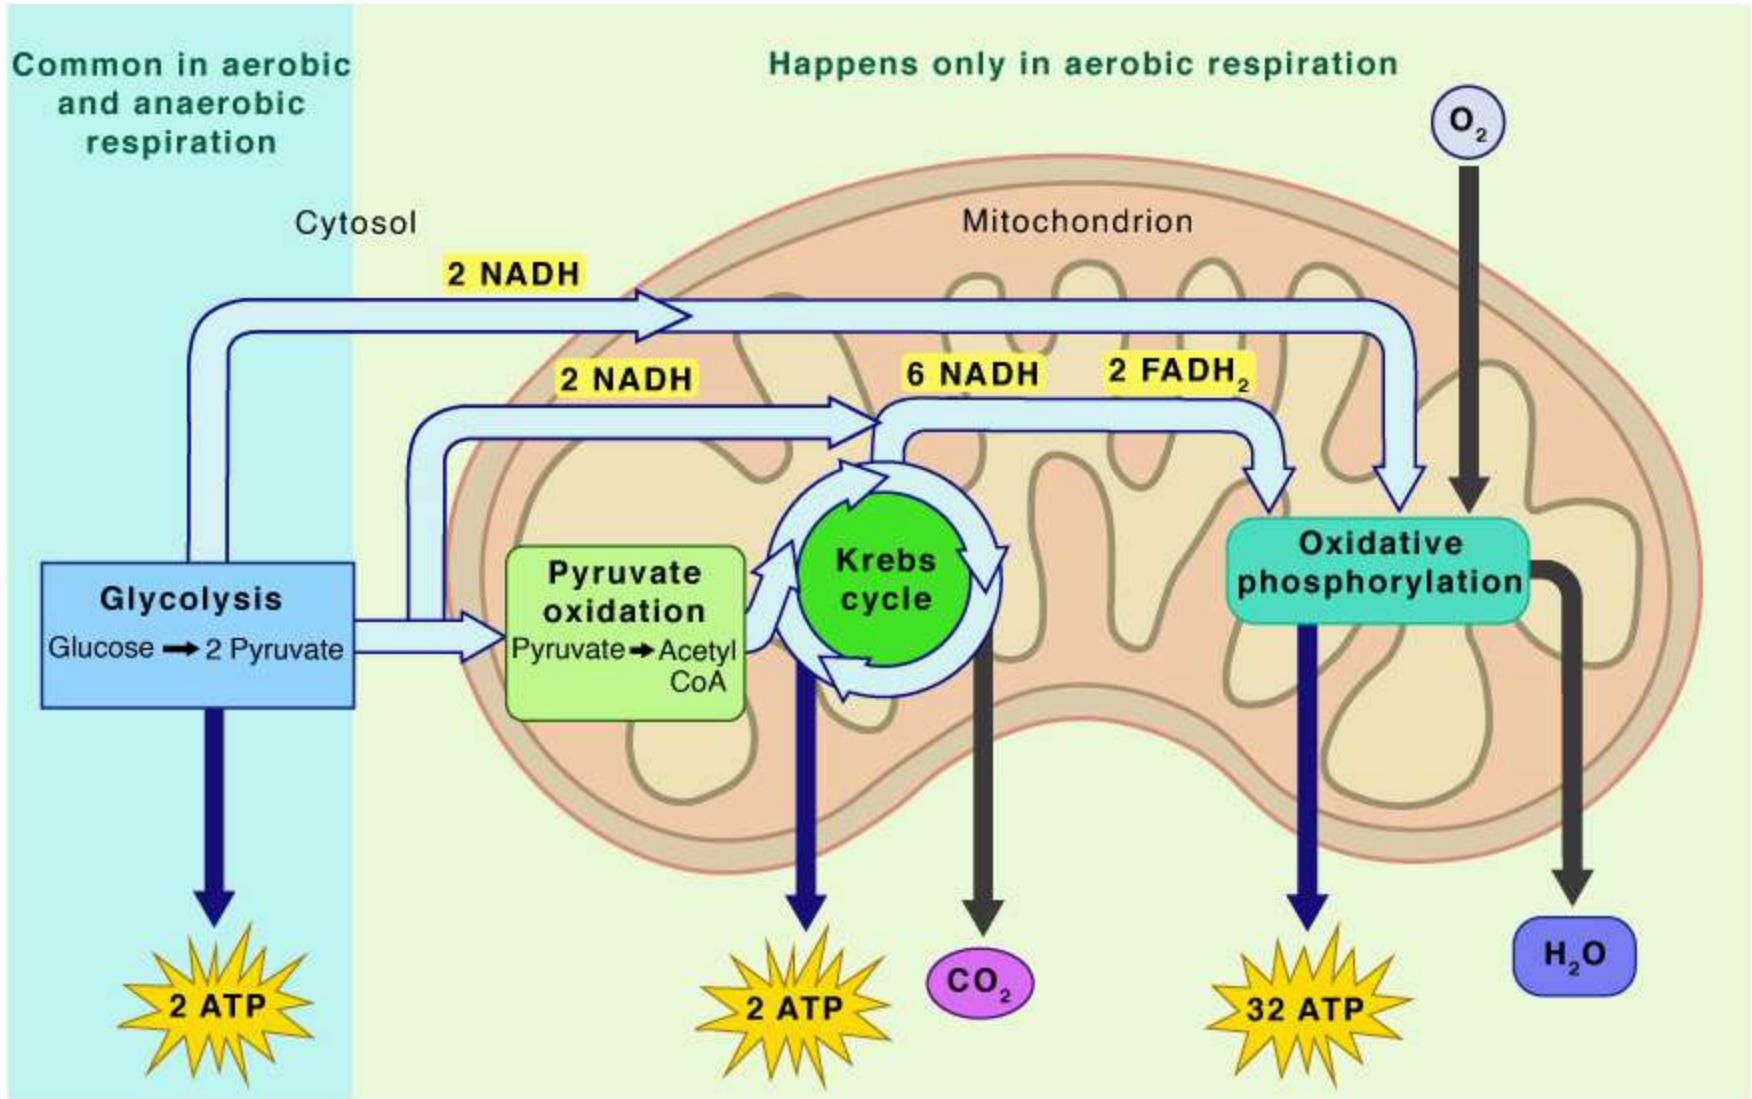
Mitochondria oxidize all macronutrient carbons for energy the same way.

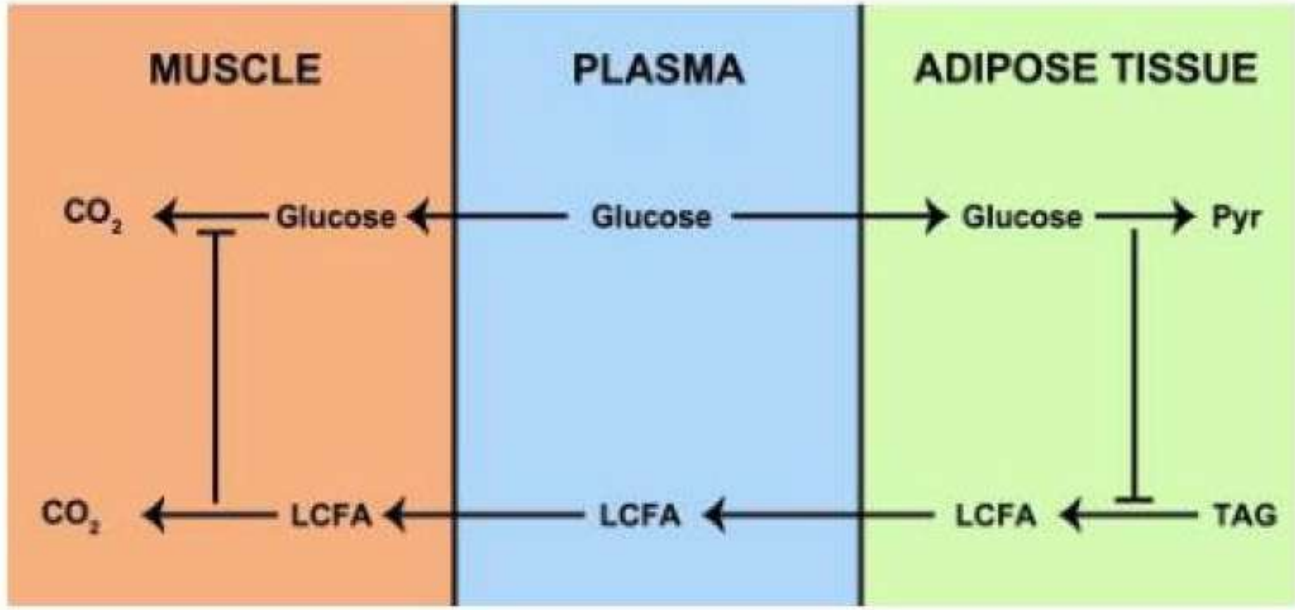


Cellular Respiration



The glucose-fatty acid (Randle) cycle

- The "cycle" also describes the control of fuel selection through the dynamic interactions between circulating concentrations of glucose and fatty acids in coordination with hormones.
- *Inhibition of glucose utilization by fatty acids is a form of glucose intolerance that resembles, or may lead to, insulin resistance.*

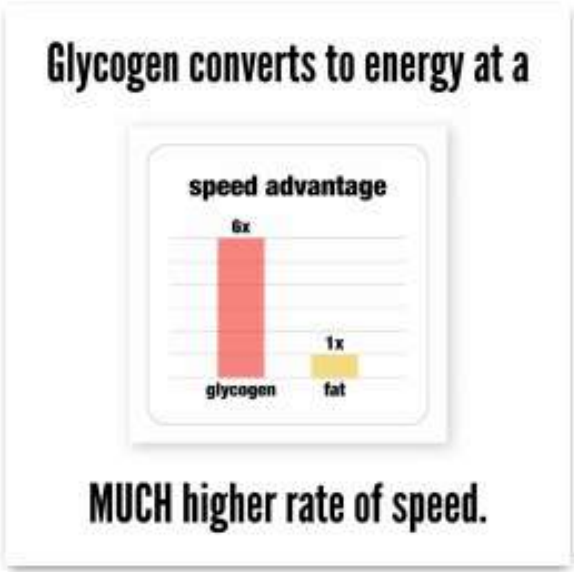


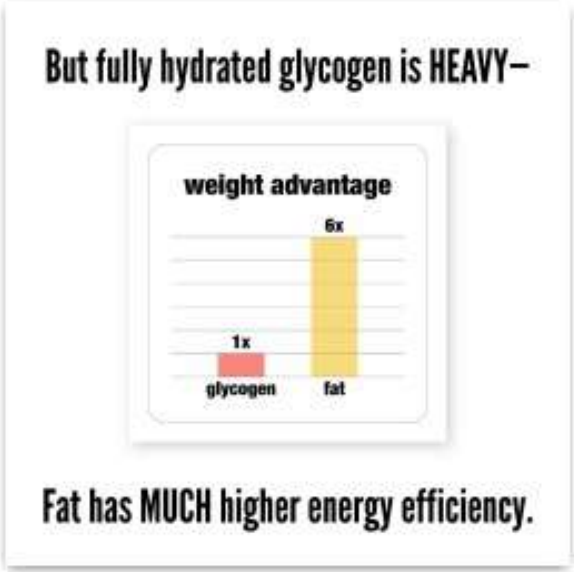
TWO COMPARTMENT SYSTEM

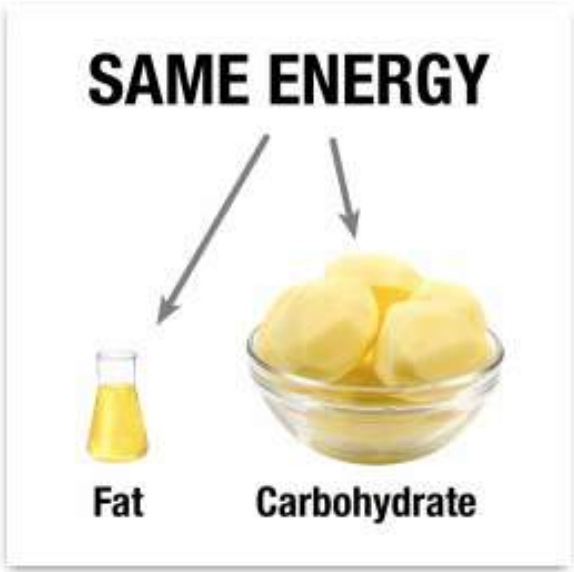
So you have two completely separate energy storage compartments in your body. Glucose (carbohydrate), which is water-soluble, is stored as glycogen (just chains of glucose) in your liver and your muscles. Fat, which is NOT water-soluble, is stored in your adipocytes. Fat storage is MUCH larger, and your body prefers to carry only about 1% of your energy as glycogen. What gives?

It turns out that glucose, from glycogen, is FAST. You can convert glucose into energy SIX TIMES faster compared to fat. So why don't we only use glycogen to store energy? Because glycogen is HEAVY! Glycogen is 'fully hydrated' (this is why we call them carboHYDRATES), which means it has a lot of water attached to it. And that water weighs a lot! So glycogen is about six times heavier than the same amount of energy stored as fat.

Glycogen, which is just chains of glucose molecules, is a sort of 'human starch' and is identical to the starch in potatoes. The fat in the lipid droplets of your adipocytes is very similar to olive oil. Note the photo below of the same amount of stored energy as olive oil versus potatoes. At six times the size and weight, you can see why your body doesn't want to carry around all your energy as glycogen. In fact, because of the weight efficiency, your body carries 100 times more fat than glycogen.

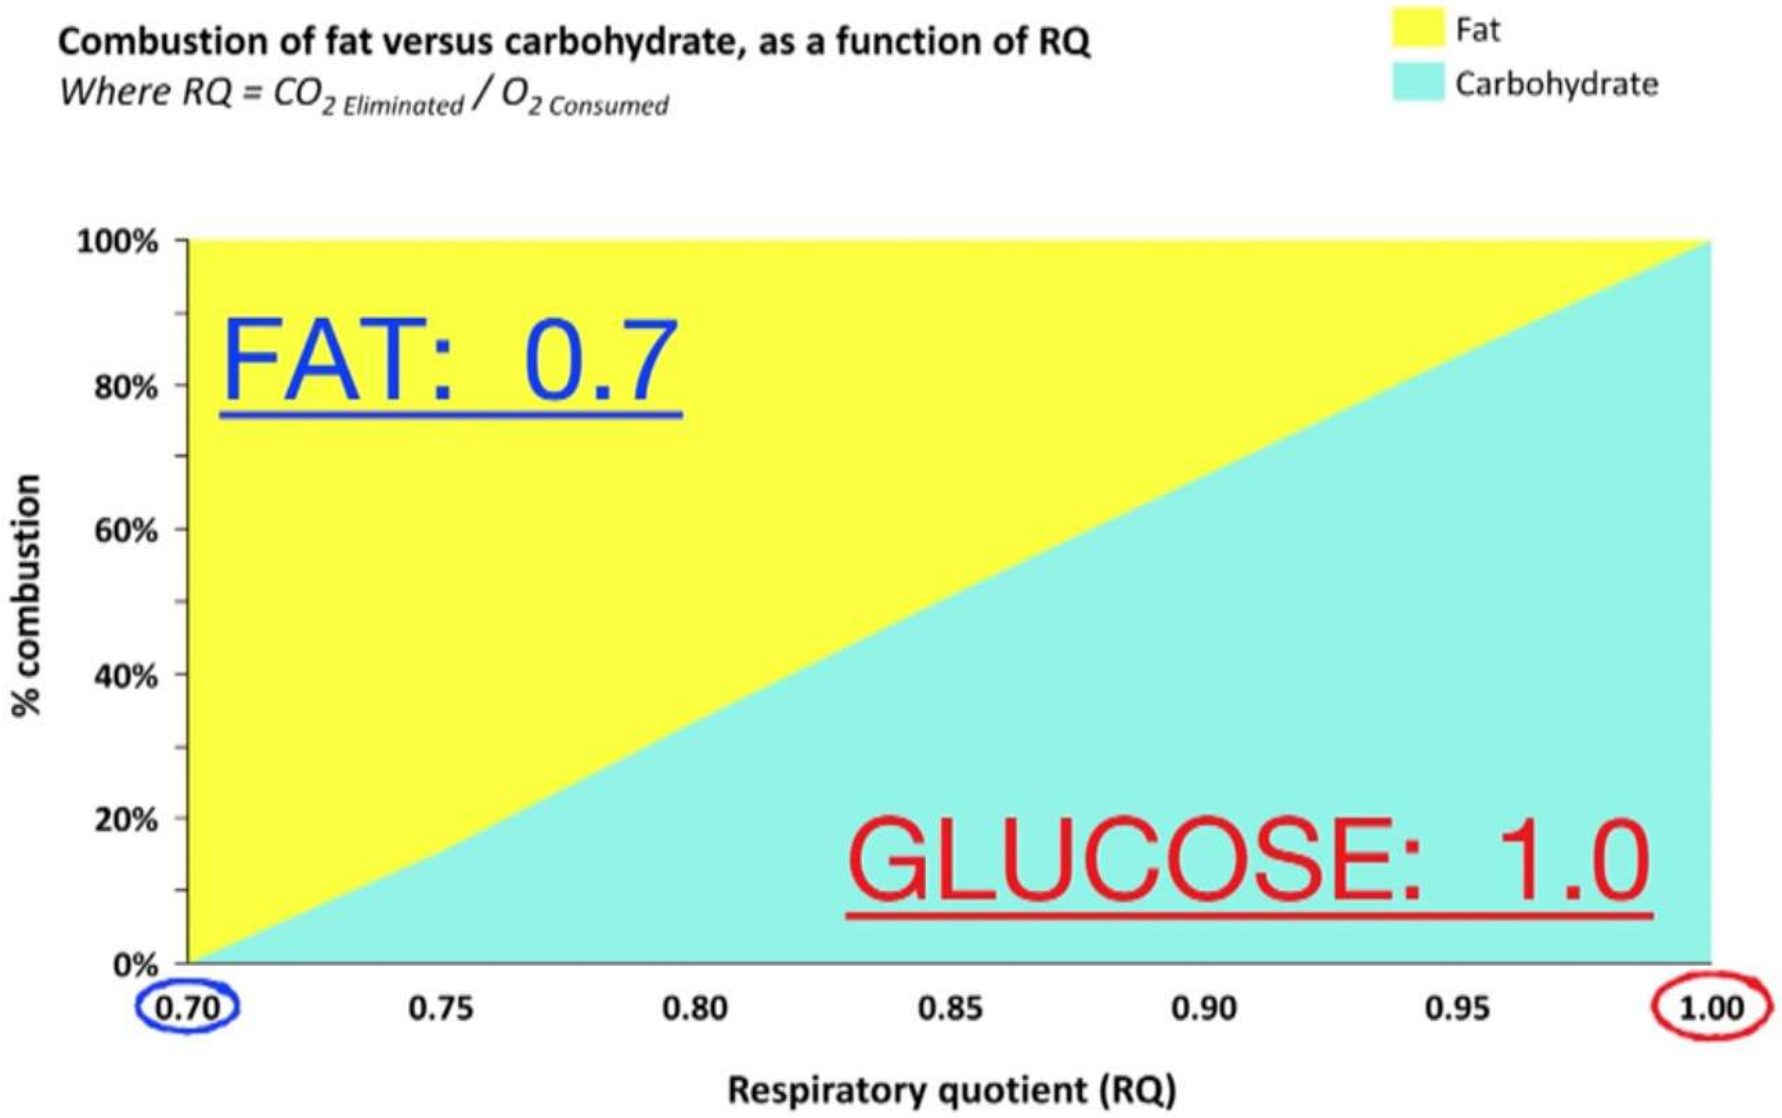


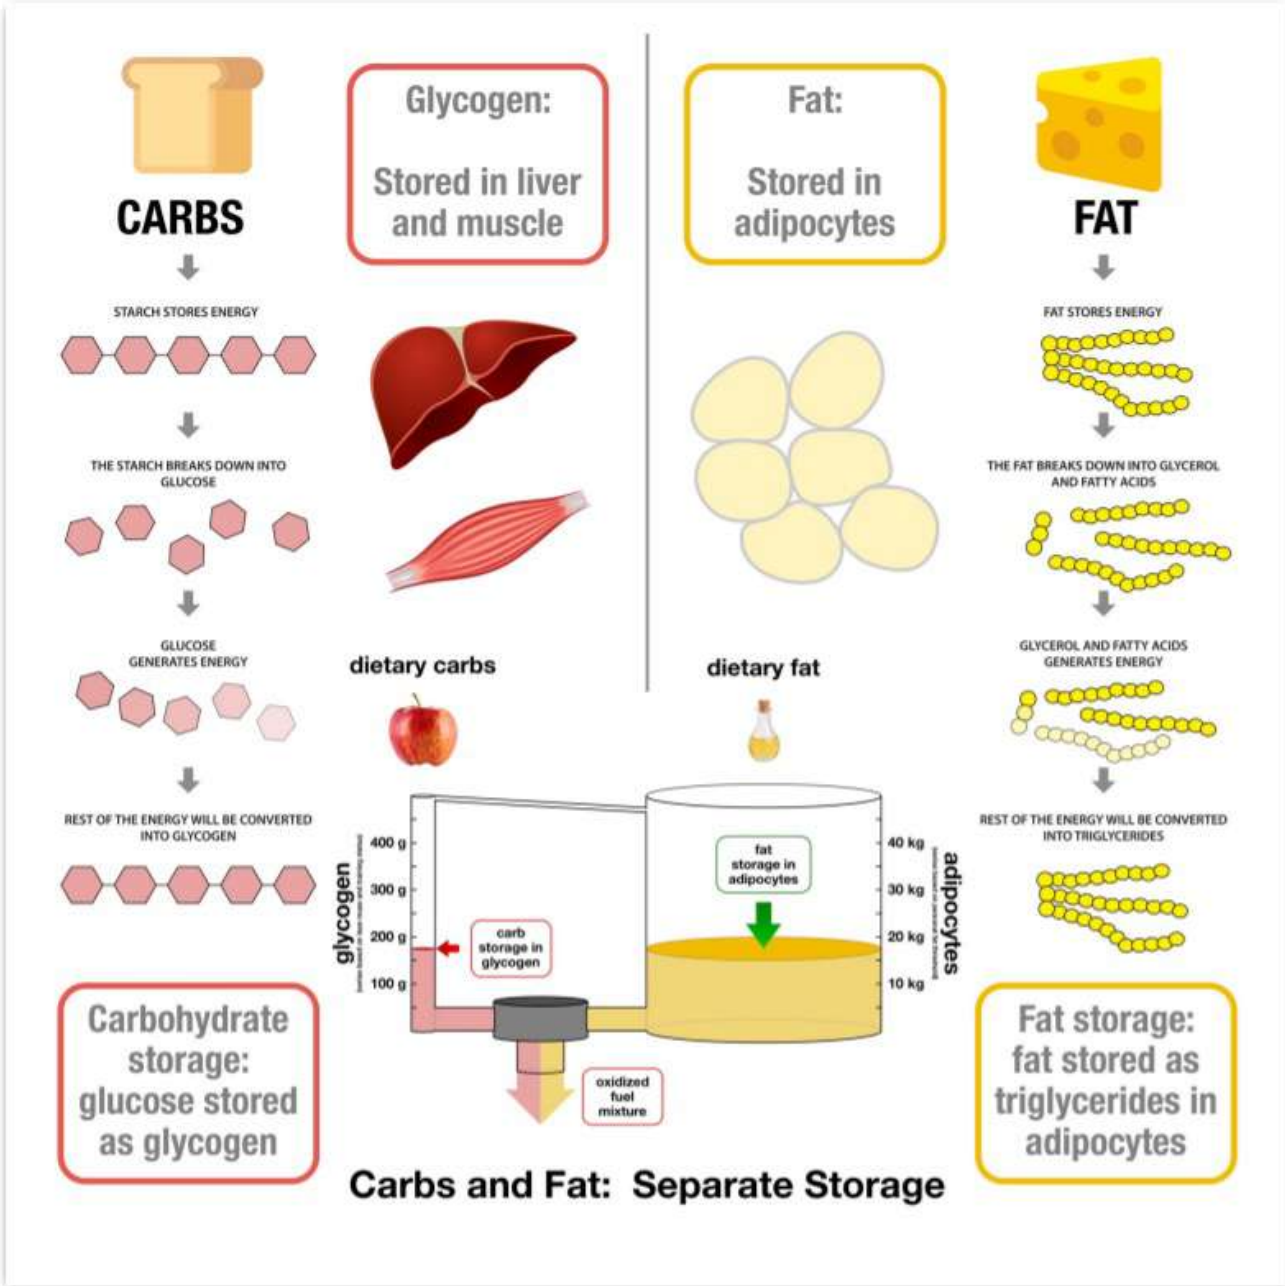




Combustion of fat versus carbohydrate, as a function of RQ

Where RQ = $CO_{2\ Eliminated}$ / $O_{2\ Consumed}$





All non-fiber carbs are broken down into simple sugars like glucose and stored as glycogen. All fats are broken down into fatty acids, then stored as triglycerides in fat cells (adipocytes).

ต้องใช้น้ำตาลเท่าไหร่?

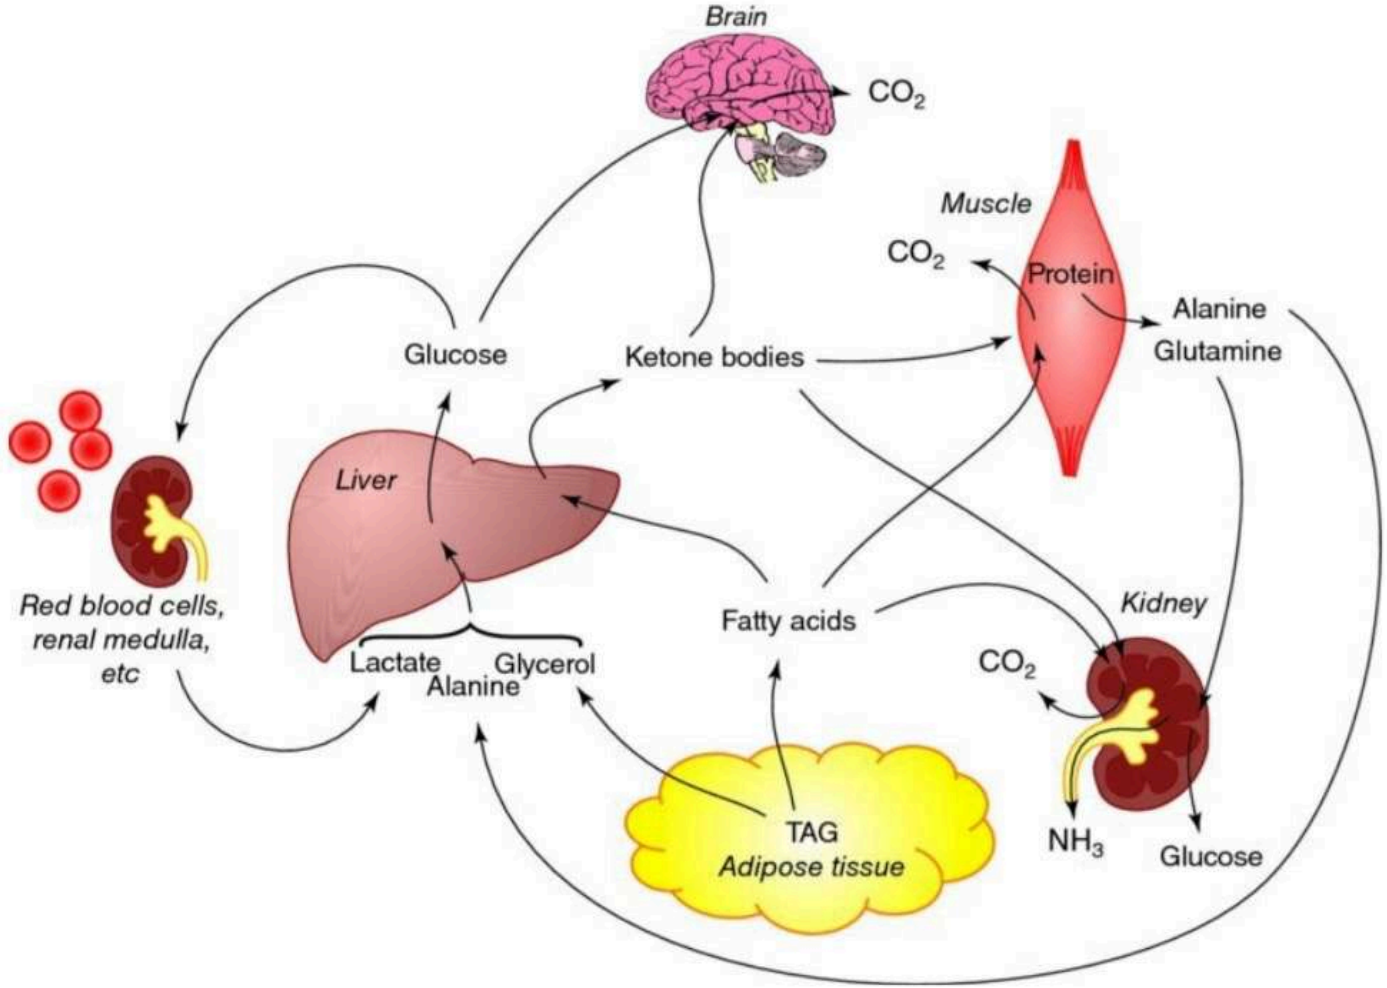

Figure 9.6 Major fuel flows in prolonged starvation. Protein (especially that in muscle) and glycerol (from lipolysis of triacylglycerol in adipose tissue) are the only long-term sources of glucose. The complete oxidation of glucose is decreased by the production of ketone bodies, which serve as an alternative fuel, for example, for the brain. Those tissues that cannot oxidise ketone bodies or non-esterified fatty acids and must therefore use glucose (e.g. red blood cells, renal medulla) produce lactate, which is 'recycled' in gluconeogenesis. The major source of fuel for oxidation is thus adipose tissue triacylglycerol (TAG), providing fuel both in the form of non-esterified fatty acids and (via the liver) ketone bodies.

There are NO essential carbohydrates!

So, why do you "need" to eat carbs?

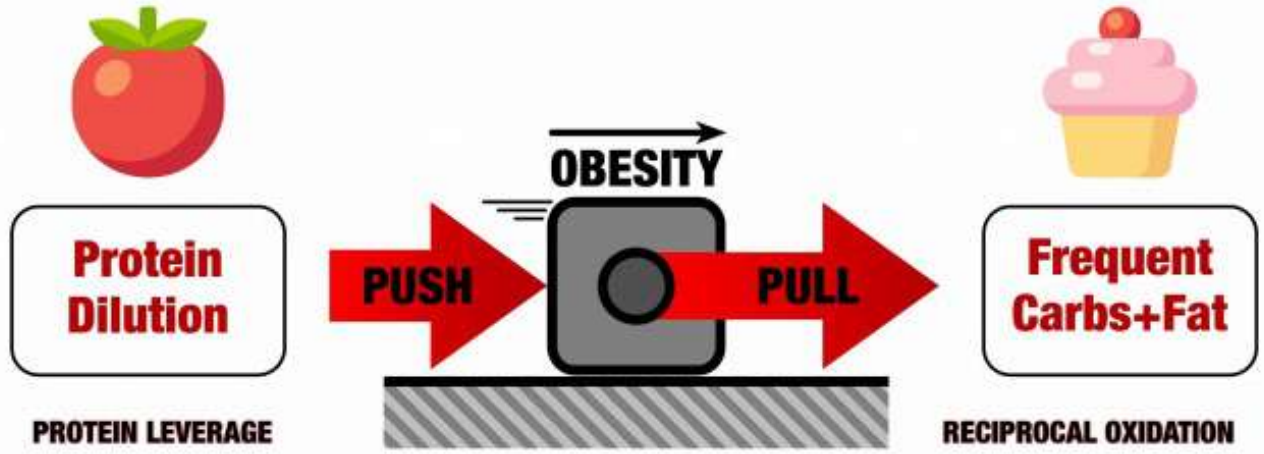
Obesity is simultaneously pushed forward by the dilution of protein and minerals, and pulled forward by the frequent co-ingestion of carbohydrates and fat.



Dilution of protein and minerals with carbohydrates and/or fats requires overingestion of this non-protein energy to achieve the same protein satiety.

Carbs displace fat oxidation and fat passively accumulates. Subsequent glucose dependence and inadequate fat adaptation drives hunger.

Potential Solutions:

1. Low carbohydrate diet.
2. Low fat diet.
3. High protein diet.
4. Avoid refined carbohydrates and fats with any whole foods diet.

Potential Solutions:

1. Low carbohydrate diet.
2. Low fat diet.
3. High protein diet.
4. Any whole foods diet.
5. Eat less frequently (intermittent).

Nutrient hunger from protein dilution and the addictive nature of carbs and fats together both drive obesity.

ABSTRACT

Objectives: National dietary guidelines were introduced in 1977 and 1983, by the US and UK governments, respectively, with the ambition of reducing coronary heart disease (CHD) by reducing fat intake. To date, no analysis of the evidence base for these recommendations has been undertaken. The present study examines the evidence from randomised controlled trials (RCTs) available to the US and UK regulatory committees at their respective points of implementation.

KEY MESSAGES

What is already known about this subject?

- Dietary recommendations were introduced in the US (1977) and in the UK (1983) to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

What does this study add?

- No randomised controlled trial (RCT) had tested

ABSTRACT

Objectives: National dietary guidelines were introduced in 1977 and 1983, by the US and UK governments, respectively, with the ambition of reducing coronary heart disease (CHD) by reducing fat intake. To date, no analysis of the evidence base for these recommendations has been undertaken. The present study examines the evidence from randomised controlled trials (RCTs) available to the US and UK regulatory committees at their respective points of implementation.

Methods: A systematic review and meta-analysis were undertaken of RCTs, published prior to 1983, which examined the relationship between dietary fat, serum cholesterol and the development of CHD.

Results: 2467 males participated in six dietary trials: five secondary prevention studies and one including healthy participants. There were 370 deaths from all-cause mortality in the intervention and control groups. The risk ratio (RR) from meta-analysis was 0.996 (95% CI 0.865 to 1.147). There were 207 and 216 deaths from CHD in the intervention and control groups, respectively. The RR was 0.989 (95% CI 0.784 to 1.247). There were no differences in all-cause mortality and non-significant differences in CHD mortality, resulting from the dietary interventions. The reductions in mean serum cholesterol levels were significantly higher in the intervention groups; this did not result in significant differences in CHD or all-cause mortality. Government dietary fat recommendations were untested in any trial prior to being introduced.

Conclusions: Dietary recommendations were introduced for 220 million US and 56 million UK citizens by 1983, in the absence of supporting evidence from RCTs.

KEY MESSAGES

What is already known about this subject?

- Dietary recommendations were introduced in the US (1977) and in the UK (1983) to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

What does this study add?

- No randomised controlled trial (RCT) had tested government dietary fat recommendations before their introduction. Recommendations were made for 276 million people following secondary studies of 2467 males, which reported identical all-cause mortality. RCT evidence did not support the introduction of dietary fat guidelines.

How might this impact on clinical practice?

- Clinicians may be more questioning of dietary guidelines, less accepting of low-fat advice (concomitantly high carbohydrate) and more engaged in nutritional discussions about the role of food in health.

INTRODUCTION

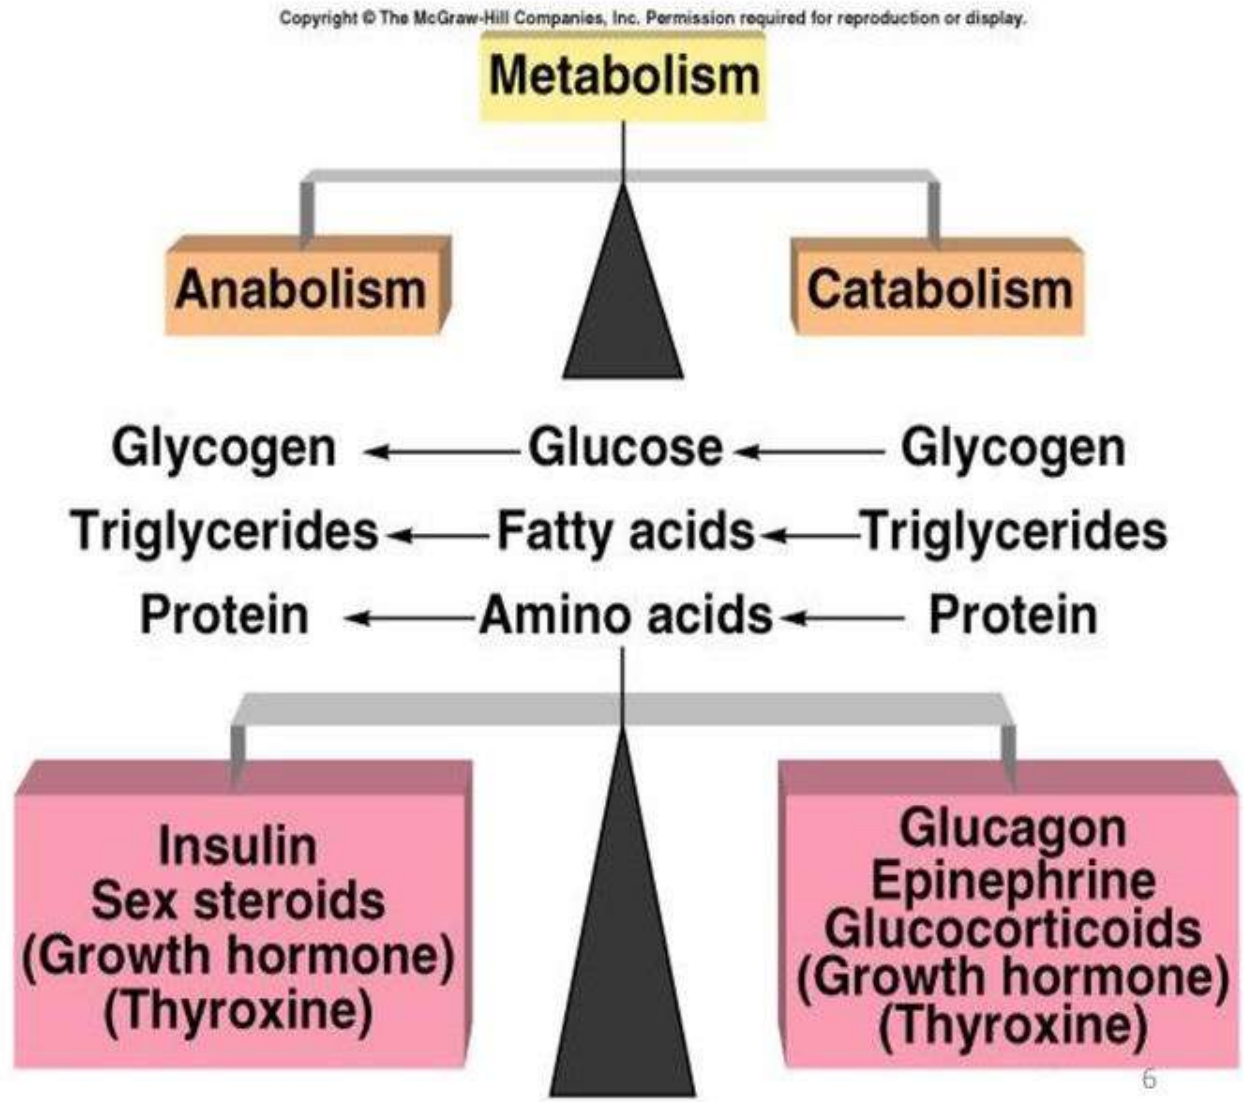
US public health dietary advice was advice issued by the National Advisory Committee on Nutritional Education in 1983.[2] The dietary recommendations in both cases focused on reducing dietary fat intake; specifically to (1) reduce overall fat consumption to 30% of total energy intake and (2) reduce saturated fat consumption to 10% of total energy intake.

The recommendations were an attempt to address the incidence of coronary heart disease (CHD). Both documents acknowledged that the evidence was not conclusive. Hegsted's introduction to the Dietary Goals for the US noted "there will undoubtedly be

How can we
make the change?

Balance Between Anabolism and Catabolism

- The rate of deposit and withdrawal of energy substrates, and the conversion of 1 type of energy substrate into another; are regulated by hormones.



Target Protein

One gram daily per pound of DESIRED body weight, from properly raised animals.

Limit Carbs

Unlimited fiber from green vegetables, but limit net carbs to less than about fifty grams daily.

Balance Fat

If you have too much fat in your body, skip high fat foods and eat only fats from eggs and lean meat.

SPECIFIC ADAPTATION TO IMPOSED DEMAND

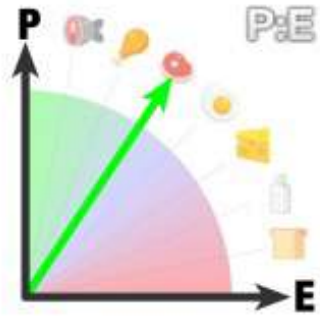
Adaptability. Humans are amazing survival machines, which is why we live in all climates, eating all diets. Your body will always adapt to meet the demands you impose upon it.

If you want your body to be better at burning fat, you only have to do one thing:

Eat fewer carbohydrates.

If you want your body to be better at burning its own stored body fat, you only have to do two things:

Eat fewer carbohydrates, and then eat less fat.



1. MAXIMIZE SATIETY.

TARGET PROTEIN AND MINERALS FOR HIGHEST NUTRIENT DENSITY.

2. MAXIMIZE FAT ADAPTATION.

USE INTERMITTENT FASTING WITH LOW CARBOHYDRATE FREQUENCY.

3. AVOID THE TRIFECTA.

HIGH CARB + HIGH FAT + HIGH ENERGY DENSITY = OVEREATING.

The three pillars of The P:E Diet.

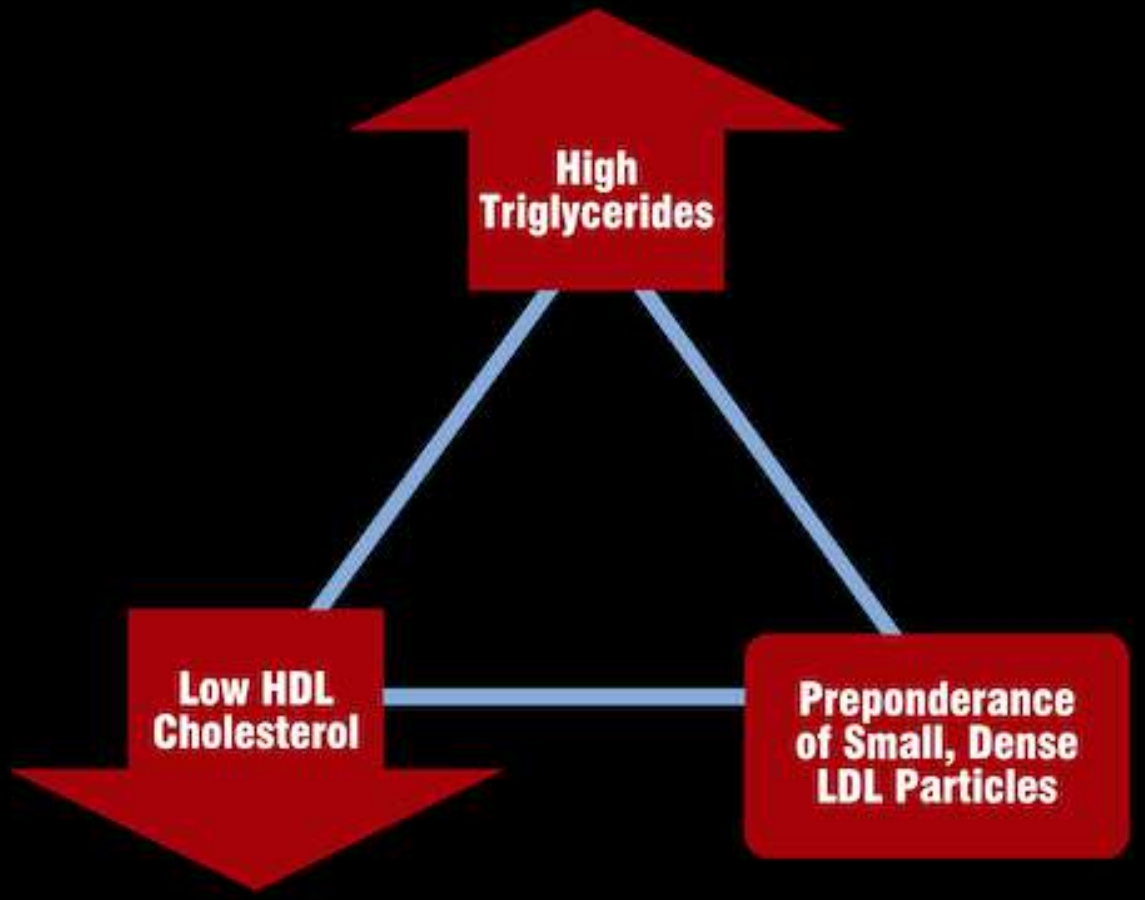
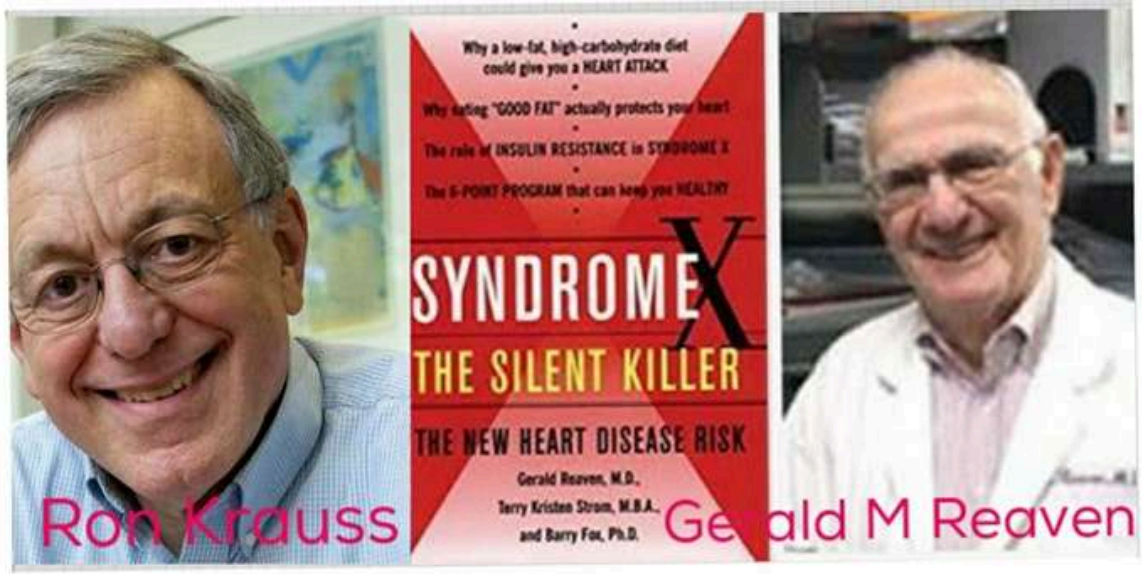
Low Carb Lipid Triad



Atherogenic Dyslipiemia



articulations and *ad hoc* modifications of their theory in order to eliminate any apparent conflict." And that's exactly what happened with metabolic syndrome and its dietary implications. The syndrome itself was accepted as real and important; the idea that it was caused or exacerbated by the excessive consumption of carbohydrates simply vanished.

Among the few clinical investigators working on heart disease who paid attention to Reaven's research in the late 1980s was Ron Krauss. In 1993, Krauss and Reaven together reported that small, dense LDL was another of the metabolic abnormalities commonly found in Reaven's Syndrome X. Small, dense LDL, they noted, was associated with insulin resistance, hyperinsulinemia, high blood sugar, hypertension, and low HDL as well. They also reported that the two best predictors of the presence of insulin resistance and the dominance of small, dense LDL are triglycerides and HDL cholesterol—the higher the triglycerides and the lower the HDL, the more likely it is that both insulin resistance and small, dense LDL are present. This offers yet another reason to believe the carbohydrate hypothesis of heart disease, since metabolic syndrome is now considered perhaps the dominant heart-disease risk factor—a "coequal partner to cigarette smok-

Atherogenic Dyslipidemia: Cardiovascular Risk and Dietary Intervention (PMID: 20524075)

CT CORONARY: CALCIUM SCORE SCANNING

Clinical Information: Coronary calcium scan was done in 50-year-old man without underlying disease for risk stratification.

Procedure: CT, non-contrast, of the heart was performed on the 64-slice CT scanner from cardiac base to apex. Patient d not receive any medication prior to the scanning.

Heart rate was 66 beats/minute.

Calcium scoring was reviewed on an advanced processing workstation.

Finding: No comparison.

CT CORONARY CALCIUM SCORING:
LM = 0
LAD = 0
LCX = 0
RCA = 0

Total calcium score = 0 using AJ-130 method.

SUMMARY: Total calcium score is 0. Patient has less likely to have obstructive CAD though cannot exclude non-calcified

สวัสดีครับคุณหมอ ยินดีด้วยนะครับที่มีผู้ติดตามคุณหมอเพิ่มมากขึ้นเรื่อยๆ ครับ. พอดีผมเพิ่งไปตรวจร่างกายมาอีกครั้ง ห่างจากครั้งที่แล้วประมาณ 1 ปี เลยอยากฝากให้คุณหมอเป็นข้อมูลเผื่อว่าจะเป็นประโยชน์. ผลเป็นดังนี้ครับ

	Feb 2020	Mar 2019
T. Choles	402	366
LDL	315	306
HDL	78	75
Triglyceride	46	56
CAC	0	0

HDL กับ Triglyceride ดีขึ้น แต่ LDL ไปต่อ. ส่วน CAC เป็น 0 เท่าเดิมครับ. (จริงๆก่อนตรวจผมกังวลค่า CAC แต่พอรู้ว่าเป็น 0 เท่าเดิม ก็สบายใจครับ)

วิทยาศาสตร์ไม่ใช่ความจริงทั้งหมด
แต่ความจริง คือ ทั้งหมดของวิทยาศาสตร์

"People who are not overweight, have low blood sugar, exercise and are on a low-carb diet typically have optimal triglycerides and HDL, and sometimes they have high LDL. Our findings show that the people who have this healthy combination of diet and lifestyle, as well as high LDL, showed no benefit from taking a statin."

Lipid levels in patients hospitalized with coronary artery disease: an analysis of 136,905 hospitalizations in Get With The Guidelines

Amit Sachdeva [1], Christopher P Cannon, Prakash C Deedwania, Kenneth A Labresh, Sidney C Smith Jr, David Dai, Adrian Hernandez, Gregg C Fonarow

Abstract

Background: Lipid levels among contemporary patients hospitalized with coronary artery disease (CAD) have not been well studied. This study aimed to analyze admission lipid levels in a broad contemporary population of patients hospitalized with CAD.

Methods: The Get With The Guidelines database was analyzed for CAD hospitalizations from 2000 to 2006 with documented lipid levels in the first 24 hours of admission. Patients were divided into low-density lipoprotein cholesterol (LDL), high-density lipoprotein cholesterol (HDL), and triglyceride categories. Factors associated with LDL and HDL levels were assessed along with temporal trends.

Results: Of 231,986 hospitalizations from 541 hospitals, admission lipid levels were documented in 136,905 (59.0%). Mean lipid levels were LDL 104.9 +/- 39.8, HDL 39.7 +/- 13.2, and triglyceride 161 +/- 128 mg/dL. Low-density lipoprotein cholesterol <70 mg/dL was observed in 17.6% and ideal levels (LDL <70 with HDL > or =60 mg/dL) in only 1.4%. High-density lipoprotein cholesterol was <40 mg/dL in 54.6% of patients. Before admission, only 28,944 (21.1%) patients were receiving lipid-lowering medications. Predictors for higher LDL included female gender, no diabetes, history of hyperlipidemia, no prior lipid-lowering medications, and presenting with acute coronary syndrome. Both LDL and HDL levels declined over time (P < .0001).

Conclusions: In a large cohort of patients hospitalized with CAD, almost half have admission LDL levels <100 mg/dL. More than half the patients have admission HDL levels <40 mg/dL, whereas <10% have HDL > or =60 mg/dL. These findings may provide further support for recent guideline revisions with even lower LDL goals and for developing effective treatments to raise HDL.

Author information

Abstract

OBJECTIVE: It is well known that total cholesterol becomes less of a risk factor or not at all for all-cause and cardiovascular (CV) mortality with increasing age, but as little is known as to whether low-density lipoprotein cholesterol (LDL-C), one component of total cholesterol, is associated with mortality in the elderly, we decided to investigate this issue.

SETTING, PARTICIPANTS AND OUTCOME MEASURES: We sought PubMed for cohort studies, where LDL-C had been investigated as a risk factor for all-cause and/or CV mortality in individuals ≥60 years from the general population.

RESULTS: We identified 19 cohort studies including 30 cohorts with a total of 68 094 elderly people, where all-cause mortality was recorded in 28 cohorts and CV mortality in 9 cohorts. Inverse association between all-cause mortality and LDL-C was seen in 16 cohorts (in 14 with statistical significance) representing 92% of the number of participants, where this association was recorded. In the rest, no association was found. In two cohorts, CV mortality was highest in the lowest LDL-C quartile and with statistical significance; in seven cohorts, no association was found.

CONCLUSIONS: High LDL-C is inversely associated with mortality in most people over 60 years. This finding is inconsistent with the cholesterol hypothesis (ie, that cholesterol, particularly LDL-C, is inherently atherogenic). Since elderly people with high LDL-C live as long or longer than those with low LDL-C, our analysis provides reason to question the validity of the cholesterol hypothesis. Moreover, our study provides the rationale for a re-evaluation of guidelines recommending pharmacological reduction of LDL-C in the elderly as a component of cardiovascular disease prevention strategies.

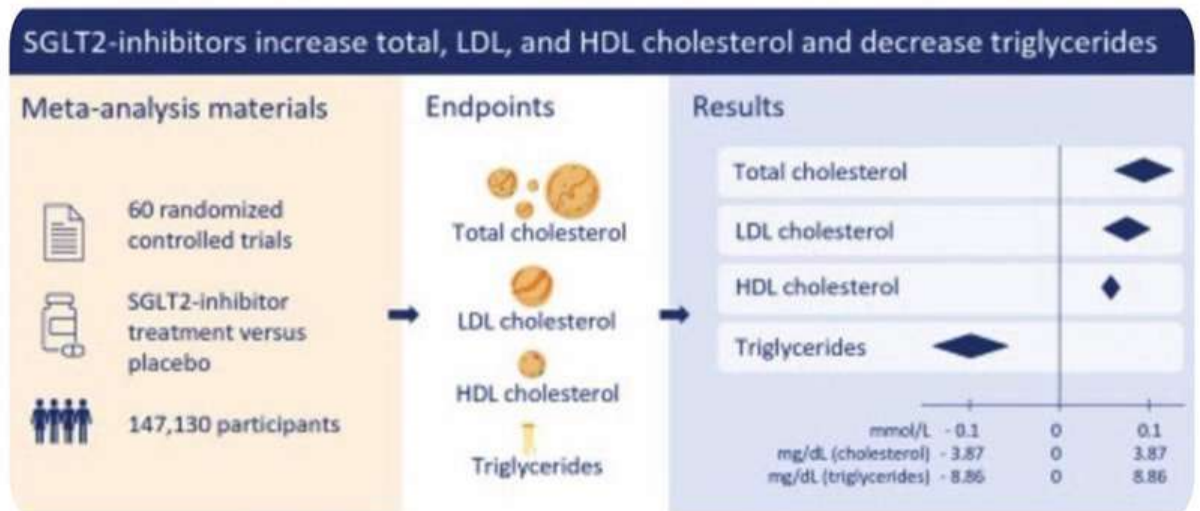
SGLT2-inhibition increases total, LDL, and HDL cholesterol and lowers triglycerides: Meta-analyses of 60 randomized trials, overall and by dose, ethnicity, and drug type

Louise E Bechmann [1], Frida Emanuelsson [2], Børge G Nordestgaard [3], Marianne Benn [4]



Conclusion: In meta-analyses, SGLT2-inhibition increased total, LDL, and HDL cholesterol and decreased triglycerides. Effect sizes varied slightly by drug dose and ethnicity but were generally robust by drug type.

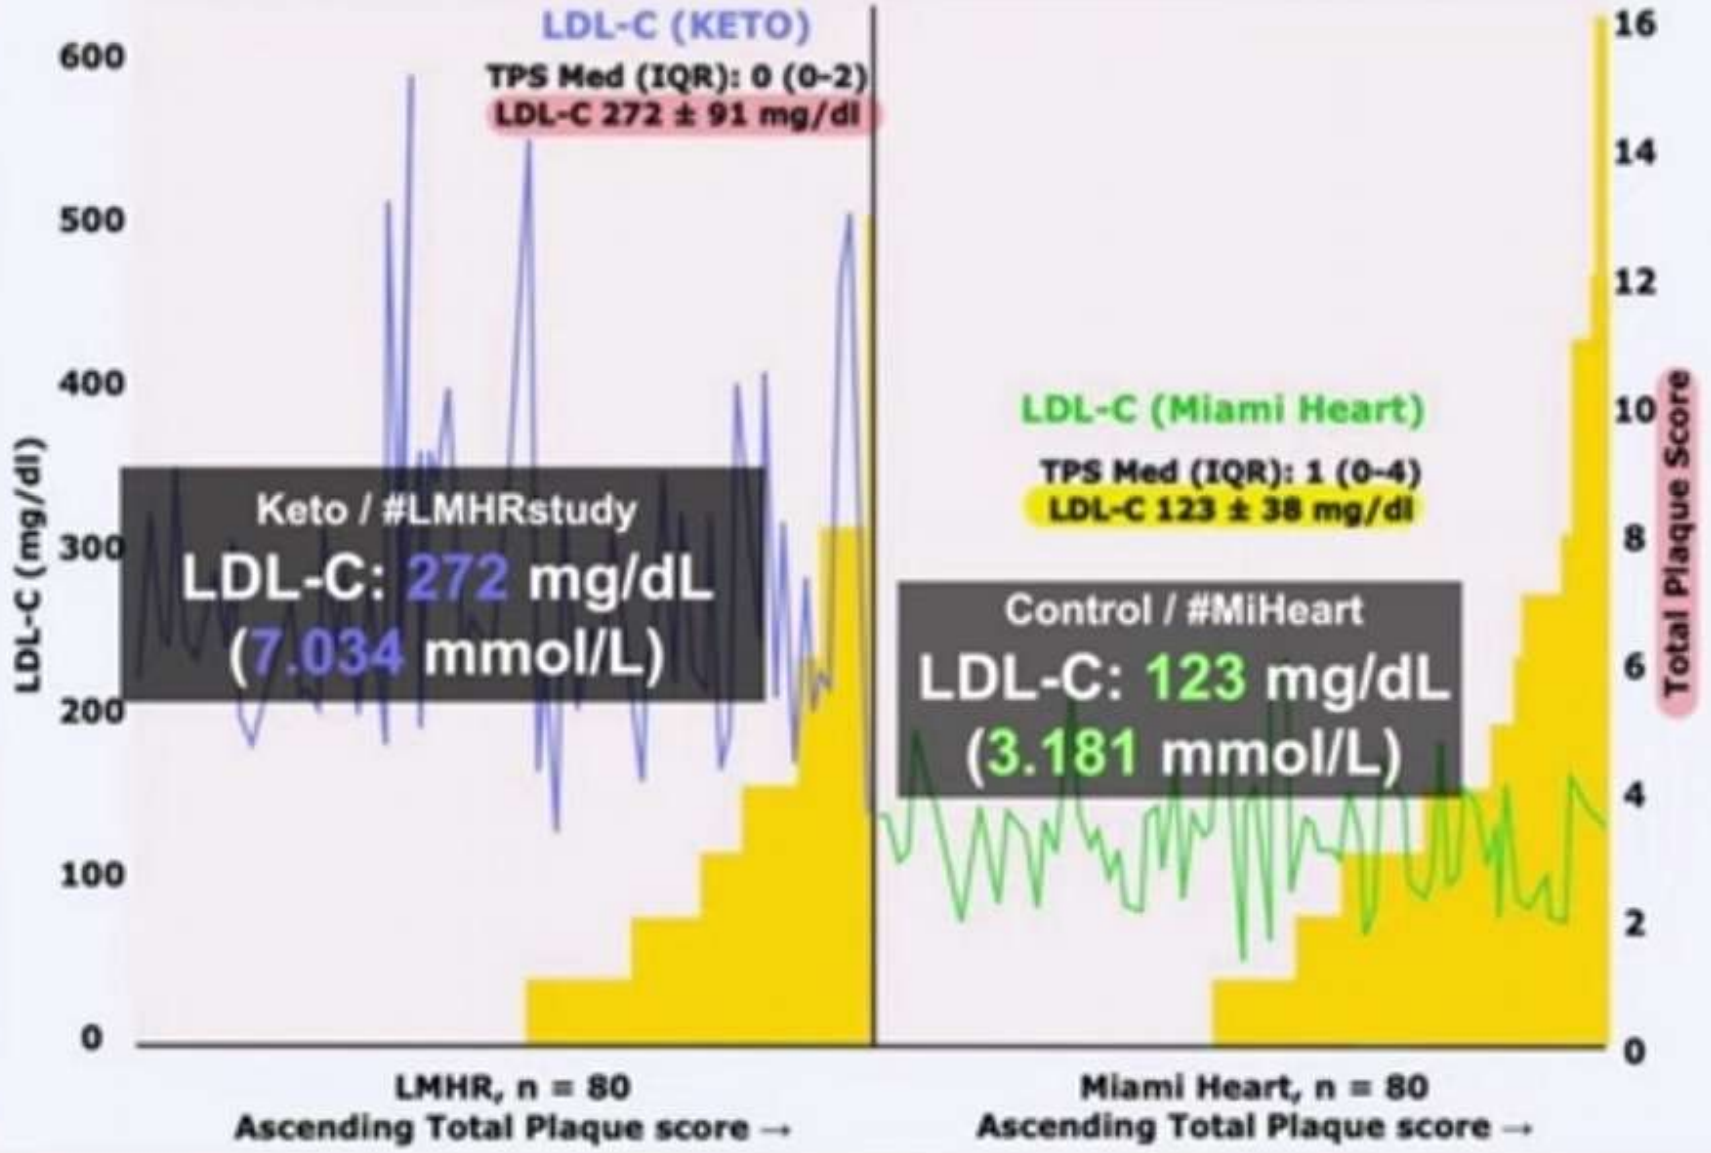
Past smoker	2	2	-



FINDINGS

At baseline, KETO subjects exhibited mean LDL-C 272 ± 91, HDL-C 90 ± 20, and TG 64 ± 23 mg/dl. Mean age and time on a ketogenic diet were 55 years, and 4.7 years.

When matched to the Miami Heart cohort (LDL-C of 123 ± 38 gm/dl), KETO group exhibited no increased plaque burden at baseline, despite almost 5 years of extreme hypercholesterolemia.

There was no significant correlation between LDL-C and CCTA-measured total plaque.

CONCLUSIONS

- After mean duration of **4.7 years** with carbohydrate restriction-induced elevations in **LDL-C (mean 272 mg/dl)**, a metabolically healthy cohort of **LMHR and near-LMHR** subjects on a **ketogenic diet did not have greater atherosclerotic burden** than participants from a population-based cohort with similar risk profiles but markedly lower LDL-C.

- There was also **no correlation between LDL-C level and plaque burden**
